9440' SHALE - brown; well indurated; homogeneous texture; dull luster; stair-step fracture; subparallel fissility; noncalcareous; poor permeability; slickensides; no cut fluorescence; extremely weak greenish residual fluorescence.

9450' SHALE - brown; hard to firm; homogeneous texture; earthy luster; noncalcareous; poor permeability; subparallel fissility; no cut fluorescence; very weak greenish residual fluorescence.

9458' CLAY - changing colors from gray-brown to gray-green; abundant glauconite, pyrite in scattered cuttings; continued abundant sloughing shale; trace light brown siliceous cuttings.

9465' SHALE - becoming commonly medium to dark brown; softer and commonly calcareous; pyritic sparkle; silty; occasional abundant glauconite; poor fissility; associated light tan, micritic to microcrystalline limestone; small, hard, blocky cuttings; dolomitic; only very weak, greenish crush cut from shale.

9475' DOLOSTONE - medium to dark brown, occasionally mottled with light brown; hard and brittle; small to large, blocky, angular cuttings; resinous to sparkling; micritic to microsucrosic; dense and nonvugular; blocky microfractures; calcitic; commonly very argillaceous; common white calcite veinlets and fracture coating; massive; even dull orange mineral fluorescence with spotty bright yellow calcite mineral fluorescence; no visible stain or cut fluorescence.

9485' MUDSTONE - medium gray-brown, dark green-brown; moderate induration; crumbly; blocky with rounded edges; high apparent clay content with earthy luster; commonly scores easily leaving waxy indentation; very calcareous; common white calcareous veins; no bedding lineation; no sample fluorescence; extremely faint diffuse pale green cut.

9495' MUDSTONE - medium to dark gray-brown; soft to firm; crumbly; tabular to blocky with common rounded edges; dull luster; slightly silty; very calcareous; floculates slightly in acid; fair shaly partings in occasional cuttings; spotty very faint yellowish sample fluorescence; very slow very diffuse pale yellow cut fluorescence; no visible cut; translucent pale yellow residual cut fluorescence.

9500' LIMESTONE - medium to dark brown; hard to very hard; commonly brittle with blocky fracture; sparkling and microcrystalline; dolomitic; very argillaceous; dense and nonvuggular; massive; occasional white calcite veinlets; even dull orange mineral fluorescence; no cut fluorescence; weak green-yellow cut fluorescence only from softer, calcareous mudstone; weak residual cut from limestone.

9510' SHALE - medium to dark brown; soft to slightly firm; slightly malleable; easily scored; earthy and slightly punky; massive, grading to claystone; slightly silty; very calcareous; occasional white inclusions and mottling; occasional calcite coating slicked surfaces; trace forams, pyrite in noncalcareous hard cuttings; no sample fluorescence; weak greenish crush cut fluorescence; fair green-yellow residual cut fluorescence.

9520' CLAY - medium brown; dominantly firm, thick; malleable to crumbly; soluble with scattered poorly soluble aggregates; nonnodular; nonexpansive; extremely calcareous; silty; abundant soft claystone cuttings; no petroleum odor or iridescence; no pops or free oil.

9535' MUDSTONE - medium to dark brown, occasionally gray-brown; dominantly slightly soft, rounded cuttings; massive; malleable; grades to claystone; commonly very calcareous; silty; occasional trace pyrite; no sample fluorescence; diffuse green-yellow crush cut fluorescence; fair yellow residual cut fluorescence.

9540' SHALE - dark brown; slightly soft to firm; flaky to blocky cuttings; breaks along rough bedding surfaces; silty; noncalcareous; reduced to trace calcareous cuttings in sample; occasionally pyritic; associated light brown dolomitic limestone; trace gray, tuffaceous and very pyritic siltstone; no oil fluorescence; weak green-yellow crush cut fluorescence; fair green-yellow residual cut fluorescence; no pops or odor.

9550' MUDSTONE - medium to dark brown; soft to firm cuttings; commonly with rounded edges; dull earthy luster; smooth to slightly silty texture; moderate to very calcareous; no distinct bedding lineation or fissility; occasional oval microfossil molds; no sample fluorescence; occasional slow wispy streaming to diffuse pale yellow cut fluorescence; no visible cut.

9555' SANDSTONE - medium gray; very fine to fine; angular to subangular; poor sphericity; moderately well sorted; moderate induration; very slightly calcareous; tight; quartz with scattered greenish gray elongated grains; no sample fluorescence or cut.

9560' SANDSTONE - light gray; very fine to fine with occasional trace medium clasts; increased loose grains in desilter; angular to subangular; poor sphericity; moderately well sorted; moderate induration becomes friable when cuttings are broken; grain packed; slightly calcareous; predominantly clear quartz and feldspar with spotty blue-green grains; no sample or cut fluorescence.

9565' SHALE - medium to dark brown; occasionally black; firm to hard; flaky to blocky; poor to no fissility; gritty and sparkling; very silty; noncalcareous; trace micromica; rare trace glauconite and sporbo; scattered forams; no oil fluorescence; diffuse yellow-green crush cut fluorescence; fair orange-yellow residual cut fluorescence.

9575' SHALE - medium to dark brown, grayish brown; firm to hard; tabular with moderately sharp edges; tough; dull luster with slight sparkle when dry; very fine silty texture; non to slightly calcareous; poor fissility; fair bedding lineation; no sample fluorescence; very slow faint diffuse pale yellow cut fluorescence; no visible cut.

9580' MUDSTONE - medium brown, grayish brown; firm, crumbly; blocky to occasionally tabular with common rounded edges; dull earthy luster with occasional microsparkles when dry; high apparent clay content; moderately calcareous in places; much less calcareous than above mudstone, clay floculates slightly in acid; no sample fluorescence; very slow very diffuse pale yellow cut fluorescence; no visible cut; weak pale yellow residual cut fluorescence.

9590' SHALY MUDSTONE - medium brown; firm to slightly hard; crumbly to tough; general overall high apparent clay content; dull earthy luster, occasional microsparkle on darker cuttings; rough uneven texture; occasional flaky fissility; calcareous with occasional microfossil molds and white streaks; no sample fluorescence; very slow diffuse pale yellow cut fluorescence; no visible cut; pale yellow residual cut fluorescence.

9600' VOLCANICS - gray; tuffaceous cuttings; firm; waxy; very slightly calcareous; commonly silty and occasionally very sandy; occasionally extremely pyritic; occasional oriented, brown, flaky mineral; bright yellow mineral fluorescence; no oil.

9610' MUDSTONE - medium brown; dominantly soft, subrounded cuttings; massive to occasional planar parting; earthy; grades to claystone; moderately silty; very calcareous; occasional white calcareous streaks; occasional calcite veinlet; no oil fluorescence; weak green-yellow crush cut fluorescence; no petroleum odor, iridescence, pops or visible oil.

9620' SHALE - medium to dark brown; slightly soft to firm; tabular to flaky; earthy to occasionally silty with probable pyritic sparkle; dominantly slightly silty; very calcareous; increasing amounts foram tests; massive to weakly bedded; commonly gradational to soft, massive, very calcareous mudstone; no oil fluorescence; weak greenish crush cut fluorescence; moderately strong green-yellow residual cut fluorescence; no visible cut.

9630' SHALE - medium brown; firm to slightly hard; crumbly; no tough or brittle cuttings; predominantly tabular with common rounded edges; dull earthy appearance with high apparent clay content; moderate to very calcareous; common microfossil molds, some oval shaped and noncalcareous; poor uneven fissility, grading to mudstone; no sample fluorescence; fast cut from mud contaminate, pits vigorously agitated bringing up sludge from bottom of pits.

9640' SANDSTONE - trace amounts; light gray-white; very fine to fine; subangular; moderately sorted; moderate induration; grain packed; calcareous cement; poor apparent porosity; quartz, feldspar, spotty dark green-gray clasts; faint yellow mineral fluorescence; no oil stains or cut fluorescence.

9655' SANDSTONE - brownish gray; fine to medium with occasionally coarse, angular to subangular grains; poor sphericity; poorly sorted; friable to moderate induration; grain packed; spotty to scattered calcareous cement; very poor to fair apparent porosity; predominantly clear to frosted quartz; scattered feldspar and spotty grayish inclusions; trace white kaolinitic cuttings with bright blue-green grains; spotty very faint yellow mineral fluorescence; infrequently very diffuse very weak yellowish cut fluorescence; no visible cut.

9665' SAND AND SANDSTONE - white; fine to medium with occasional coarse; angular to subrounded, predominantly subangular; poor sphericity; moderately sorted; predominantly loose sand with occasional moderately indurated grain packed sandstone cuttings with poor to fair apparent porosity; very calcareous with abundant white kaolinitic cuttings; predominantly clear quartz with minor grayish lithic fragments; no visible oil stains; scattered moderate to occasionally bright white-yellow mineral/sample fluorescence; very slow very diffuse pale yellow cut fluorescence becoming slightly more intense with time; no distinct improvement with crushing; no visible cut; moderately bright translucent pale to light yellow residual cut fluorescence.

9700' SHALE - (mudstone) - dusky yellowish brown; hard; tough; tabular; dull luster; silty; finely abrasive texture; slightly to moderately calcareous; no bedding lineation; trace fecal pellet; moderately calcareous; trace streaky faint yellow sample fluorescence; very slow diffusely streaming very pale greenish yellow cut fluorescence; no visible cut.

9705' MUDSTONE - medium to dark brown; firm to hard; very small blocky cuttings with slightly rounded to sharp edges; earthy; common clay in sample; most probably derived from grinding of mudstone by Strato-pak type bit; non to very slightly calcareous; no apparent banding or fissility.

9715' SHALE - medium to dark brown; soft with good flaky fissility; bedding commonly pronounced; occasional weak laminations; earthy; very clayey; noncalcareous; occasional glauconite grains; occasional phosphatic fish remains on bedding surfaces; occasional black, probably carbonaceous material; no sample fluorescence; weak greenish cut fluorescence; common bit gouge.

9720' CLAY - medium gray-brown; soft, slightly thin; smooth; poor cohesion and malleability; very soluble; nonexpansive; slightly calcareous; very silty; probably produced by strata-pak bit action; no iridescence, pops; strong pungent petroleum odor.

9730' SHALE - medium to dark brown; soft to firm; earthy and very clayey; fissile with pronounced bedding; becoming very calcareous; slightly silty; no sample fluorescence; fair greenish yellow crush cuts; no oil in desilter sand.

9740' CLAY - medium brown; soft, slightly thick; slightly crumbly to dominantly smooth; nonnodular; derived from shale; soluble; nonexpansive when rehydrated; slightly to moderately calcareous, becoming less calcareous; very silty; rare quartz sand; no pops or iridescence, no oil fluorescence; acrid petroleum odor.

9745' SAND - desilter sample; clear, white, trace green; fine to medium; angular to subangular; spherical to occasionally prismoidal; well sorted desilter sample; quartz with scattered feldspars; trace calcite; no sample or cut fluorescence.

9750' SHALE - (mudstone); dusky yellowish brown, dark grayish brown; firm; crumbly; rich earthy luster; slightly silty; predominantly noncalcareous; occasional trace spotty oval shaped glauconite grains, possibly replaced forams; trace of lenses or pockets of fine sandstone; common striations and lineation caused by the bit which also imparts false fissility; trace faint yellow sample fluorescence from sandy areas; overall no sample fluorescence; very weak diffuse pale yellow transparent cut fluorescence; no visible cut.

9755' SHALE - dark brown; firm, crumbly; predominantly tabular; earthy luster; silty; high apparent clay content; noncalcareous; rare microglauconite; common lineation and possible false fissility; imparted by bit; no sample fluorescence; very slow extremely diffuse tinge of yellowish cut fluorescence; no visible cut.

9765' SHALE - dark grayish brown; firm; crumbly to very slightly brittle; tabular; dull luster with faint microsparkle when dry; silty; non to very slightly calcareous; very slightly expansive in HCl; cuttings have fine flaky appearance and apparent good fissility, both probably from Strata-pak bit; no sample fluorescence; slow to moderately fast streaming light yellow cut fluorescence; very pale straw visible cut from bulk; pale greenish yellow to bright orangish yellow residual cut fluorescence with pale brown ring; slight petroleum odor from blender.

9770' SHALE - dark grayish brown; firm; crumbly, becoming much firmer when dry; tabular; earthy; slightly silty; very slightly calcareous; spotty trace of microscopic dark green-black oval shaped glauconite; continued lineation from bit; no sample fluorescence; slow to moderately fast weak diffuse pale yellow to fast diffuse moderately bright greenish yellow cut fluorescence; very pale straw visible cut from bulk; moderately bright yellow residual cut fluorescence with pale brown residual ring; possible trace contaminates; faint tarry odor from blender.

9780' SHALE - dark grayish brown, dark brown; firm to slightly hard when dry; tabular, crumbly to slightly tough; dull luster; silty texture with very fine grainy appearance; moderately calcareous in places; locally abundant glauconite; no sample fluorescence; moderately fast wispy streaming transparent greenish cut fluorescence; pale straw visible cut from bulk; moderately bright translucent yellow residual cut fluorescence; no obvious trace X-Pel-G; weak tarry odor from blender with acrid odor.

9790' TUFF - trace amount; medium orange-brown; firm; waxy; easily scored; commonly slightly grainy; noncalcareous; disseminated pyrite; weak, parallel microbanding; very bright yellow mineral fluorescence; no oil or cut fluorescence; fair cuts from shale.

9800' SHALE - dark brown; slightly soft to moderately firm; dominantly easily broken cuttings; cuttings predominantly curved, elongated, heavily gouged and grooved; earthy and very clayey; noncalcareous; occasional small, very calcareous cuttings; slightly silty; occasional phosphatic debris; no oil fluorescence; slow blooming green-yellow crush cut fluorescence; moderate to strong yellow residual cut fluorescence; straw dry cut ring; cuts best from dry cuttings.

9807' CLAY - medium gray-brown; soft and thin; smooth; poor cohesion; very soluble; nonexpansive when rehydrated; derived from shale; noncalcareous; extremely silty to very finely sandy; no oil fluorescence or visible oil in mud; no iridescence or fluorescent pops; strong, acrid petroleum odor from blender.

XRD and SEM Report from Halliburton Chemical Laboratory

FORM 1012 R-6

LITTLE'S 112485 6M 9/80

CHEMICAL RESEARCH AND DEVELOPMENT DEPARTMENT

HALLIBURTON SERVICES
DUNCAN, OKLAHOMA

LABORATORY REPORT

No. T11-A178-85

To Mr. Mike Eberhard

Halliburton Services

Bakersfield, CA

Date October 14, 1985

This report is the property of Halliburton Services and neither it nor any part thereof nor a copy thereof is to be published or disclosed without first securing the express written approval of laboratory management; it may however, be used in the course of regular business operation by any person or concern and employees thereof receiving such report from Halliburton Services.

We give below results of our examination of formation core samples.

Submitted by Shell Exploration and Production Company

Marked Well: 43-27
Location: North Belridge; Kern County, CA
Formation: Oceanic
Depth: 8,354-9,681 feet
Samples Received: August 23 and September 27, 1985
Los Angeles Division Reference No: CBB-A98-0394-0822-85

Purpose

The purpose of this report is to analyze the submitted samples. The tests include x-ray diffraction, acid solubility, immersion and scanning electron microscope examination.

Discussion

The results of the requested tests are included in the Data Section of this report.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data

Core Description

Sample No. 1 at 9,681 feet SANDSTONE - Light grey color, fine clay and quartz debris present as matrix, secondary quartz overgrowth may also be present as cement. Poor visible porosity.

Sample No. 2 at 9,126 feet SANDSTONE - Light grey color, fine grained, secondary quartz overgrowth present. Fair to poor visible porosity.

Sample No. 3 at 8,830 feet SANDSTONE - Grey color, fine grained, secondary quartz overgrowth present. Poor visible porosity.

Sample No. 4 at 8,727 feet SANDSTONE - Grey to light grey color, fine grained, clay appears to be present in the matrix. Poor visible porosity.

Sample No. 5 at 8,354 feet SANDSTONE - Similar to Sample No. 3 but finer grained.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Qualitative X-ray Diffraction and Acid Solubility Analyses

Purpose: To identify the types and relative quantities of minerals in the formation sample.

Procedure: A pulverized one gram sample is placed in an x-ray beam and rotated through an arc. The x-ray beam is diffracted by the sample and the diffraction patterns are recorded.

Results: The diffraction patterns are used to identify the types of minerals present and their relative quantities. The relative quantities for the submitted samples are as follows:

Formation	Oceanic	Lower 64 "W" Sand	Upper "W" Sand	Upper 64 "U" Sand	Aqua
Sample No.	1	2	3	4	5
Depth (feet)	9,681	9,126	8,830	8,727	8,354
HCl Solubility*	1.5%	0.8%	1.5%	1.3%	2.0%
Quartz	65-80%	35-45%	40-50%	50-65%	50-65%
Feldspar	10-15%	45-55%	40-50%	35-45%	25-35%
Calcite	0.5-2%	-	-	-	-
Dolomite	-	-	-	-	-
Kaolinite	5-10%	2-5%	2-5%	-	2-5%
Illite	0.5-2%	0.5-2%	0.5-2%	0.5-2%	2-5%
Smectite	-	-	-	-	-
Mixed Layer	0.5-2%	2-5%	2-5%	0.5-2%	0.5-2%
Chlorite	-	-	-	-	-

*One gram of sample is added to 0.5N HCl. After reaction, the excess acid is titrated with 0.2N NaOH. The results are calculated and reported as calcium carbonate. (Note: a pure dolomite will be reported as 108%).

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Immersion Test

Purpose: To observe the effect of various base fluids on core chips from selected representative cores.

Procedure: Freshly broken chips from cores are immersed in test fluids; one chip per fluid in a 30 ml beaker. The samples are then placed in a vacuum for one hour. After that time an observation is made to evaluate the effect of the fluid on the core chip.

Results: Released fines from a core chip may indicate formation sensitivity to the test fluid.

Effects of immersion under vacuum at 180°F (test temp.) for one hour in the following fluids:

Sample No.	Depth (feet)	Fresh Water	2% KCl Water	2% KCl Water*	7½% MCA Acid	6.0% HF Acid	Kerosene
1	9,681	N	N	N	V	V	N
2	9,126	V	N	V	V	V	N
3	8,830	V	V	N	V	V	N
4	8,727	V	N	N	V	V	V
5	8,354	V	V	N	V	V	N

N - No fines released.
V - Very small amount of fines.
S - Small amount of fines.
M - Moderate amount of fines.
L - Large amount of fines.
P - Partially disintegrated.
CD - Completely disintegrated.
GR - Gelatinous residue formed.
PD - Partially dissolved.
C - Completely dissolved.

*0.5 gallon CLA-STA II compound per 1,000 gallons.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Scanning Electron Microscope (SEM) Examination

Purpose: To provide a greatly magnified view of a core sample. Minerals present in the sample can be identified and their location observed.

Procedure: A core chip with a freshly broken surface is required for this examination. The sample is coated with a gold palladium alloy and placed in the vacuum chamber of the SEM. The core chip is viewed at a high magnification and a photomicrograph is taken. An associated energy dispersive x-ray (EDX) is used to help identify the mineral content of the sample.

Results: The framework grains can be identified and their size approximated. The location of the clay minerals within the sample can be observed. The SEM can produce, in effect, a pseudo three-dimensional view of formation pore spaces. The area of the sample viewed is very small and may not clearly characterize the entire formation.

Sample No: 1
Depth: 9,681 feet

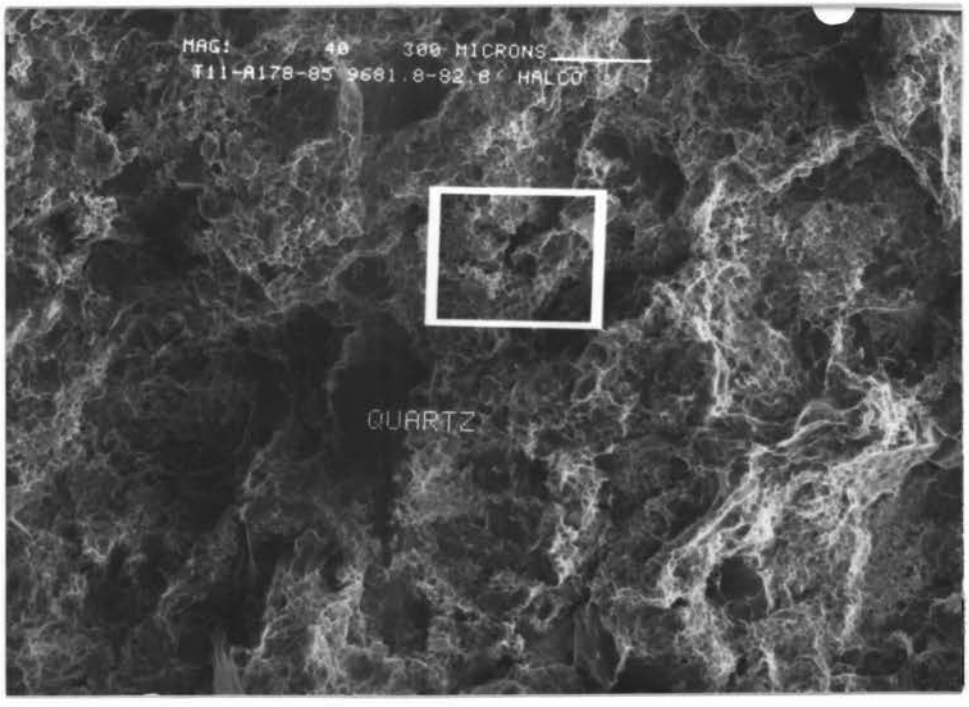

Figure No. 1; Negative No. 21805-9070; Magnification 40X

Framework grains are difficult to distinguish in this low magnification view.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Scanning Electron Microscope Examination Cont'd

Sample No: 1
Depth: 9,681 feet

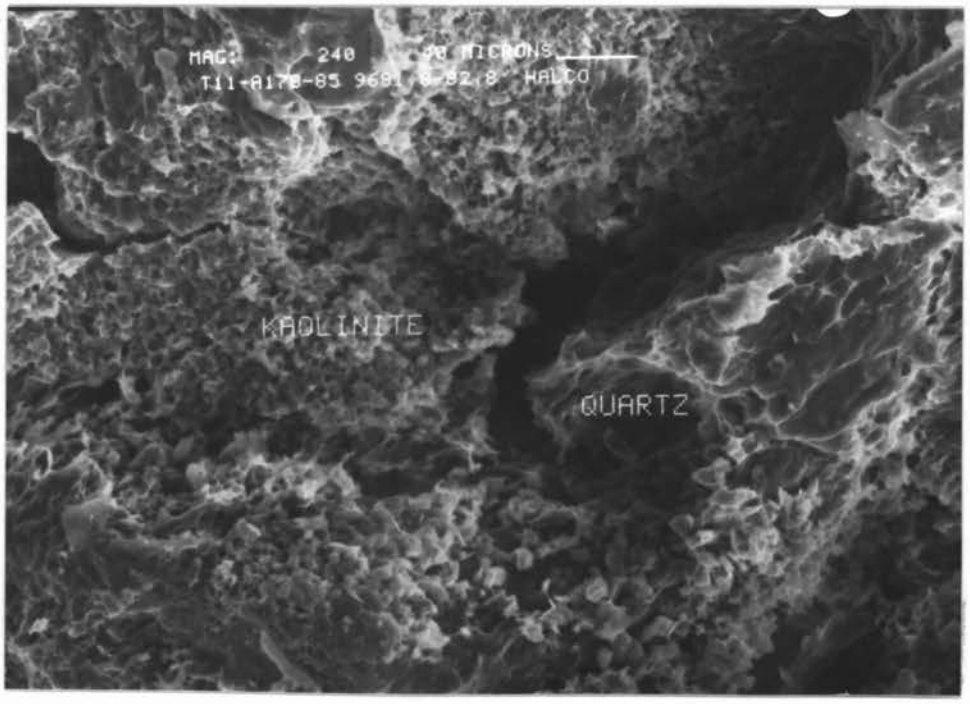

Figure No. 2; Negative No. 21805-9069; Magnification 240X

This view shows kaolinite covering the framework grain surface and the fair to poor visible porosity.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Scanning Electron Microscope Examination Cont'd

Sample No: 2
Depth: 9,126 feet

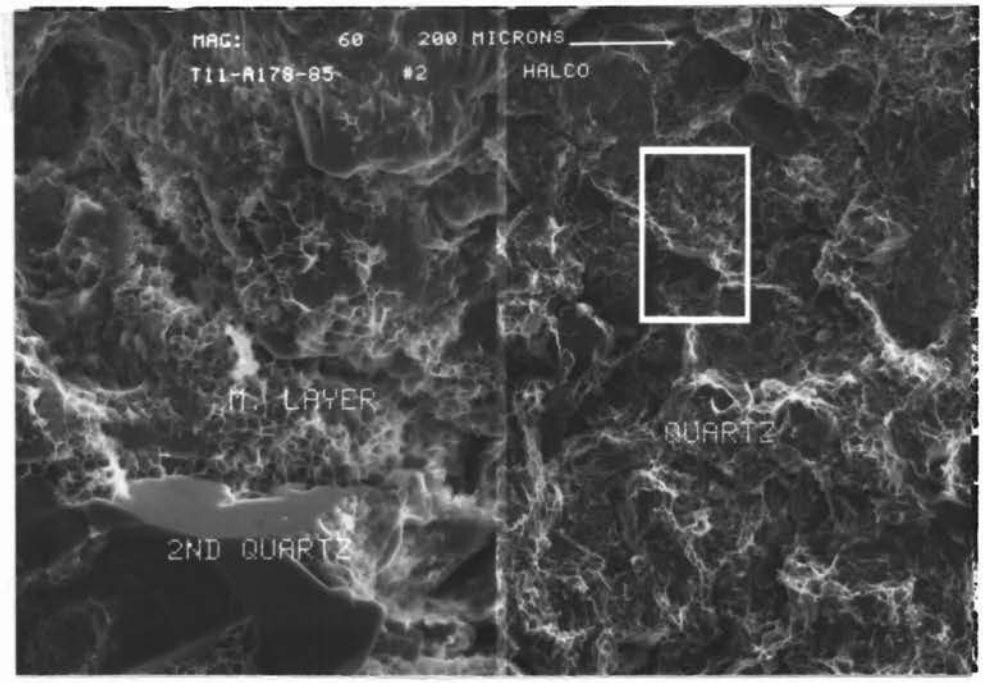

Figure No. 3; Negative No. 21805-9143; Magnification 60X and 300X

This sample is similar to Sample No. 1 in having poorly distinguished framework grains. High magnification view shows secondary quartz overgrowth and a highly smectitic mixed layer clay covering the sample.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Scanning Electron Microscope Examination Cont'd

Sample No: 3
Depth: 8,830 feet

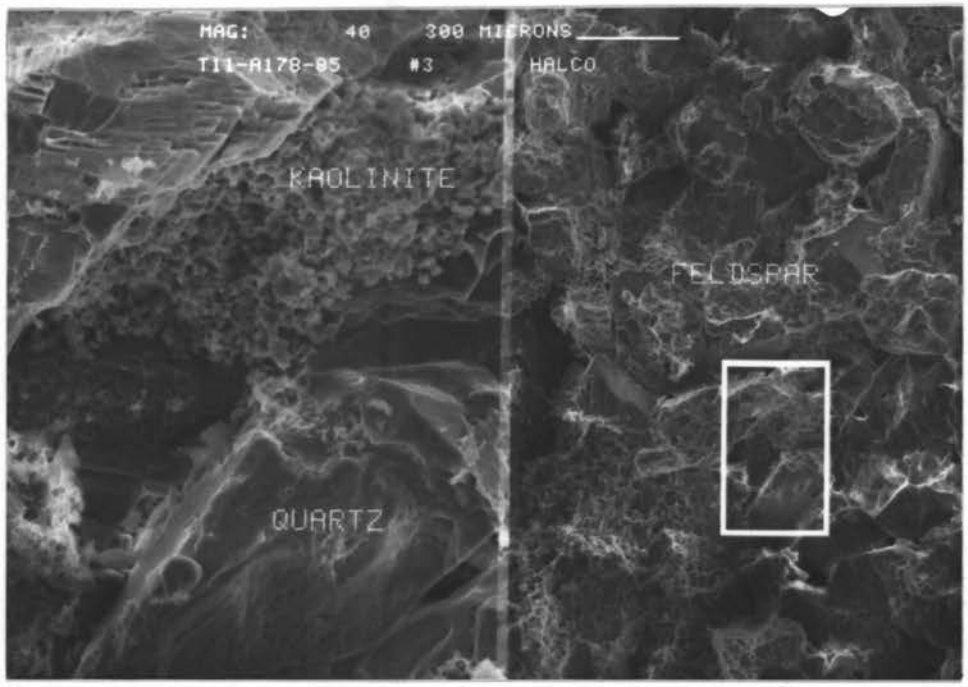

Figure No. 4; Negative No. 21805-9142; Magnification 40X and 200X

This view shows the fine to medium sand size grains of quartz and feldspar with pockets of kaolinite and small amounts of secondary quartz overgrowth.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Scanning Electron Microscope Examination Cont'd

Sample No: 4
Depth: 8,727 feet

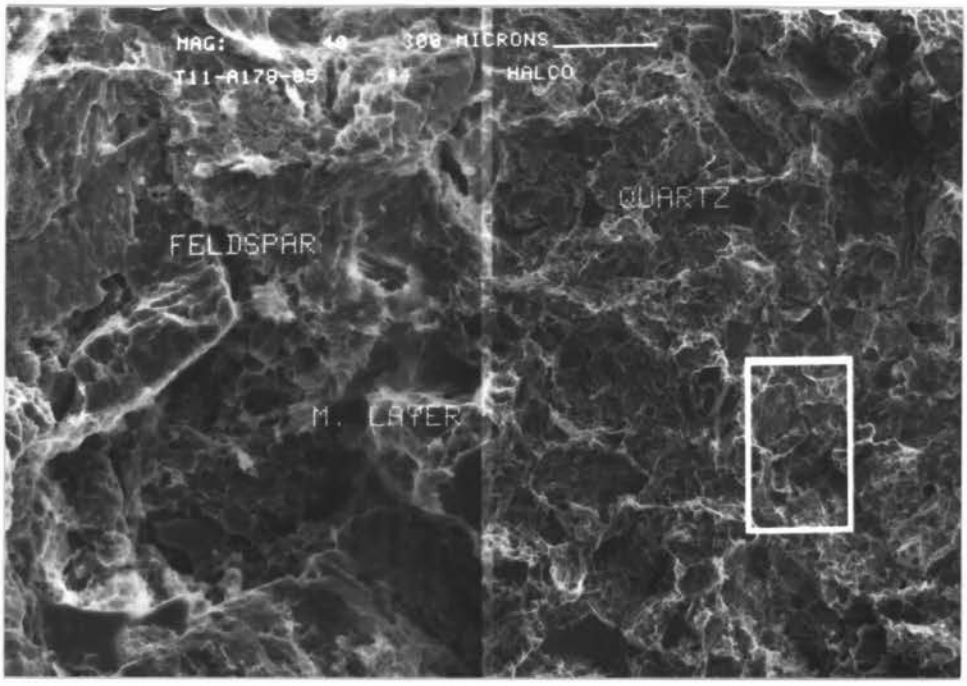

Figure No. 5; Negative No. 21805-9141; Magnification 40X and 200X

This sample has poorly distinguished framework grains and trace of illite and a highly smectitic mixed layer clay.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Scanning Electron Microscope Examination Cont'd

Sample No: 5
Depth: 8,354 feet

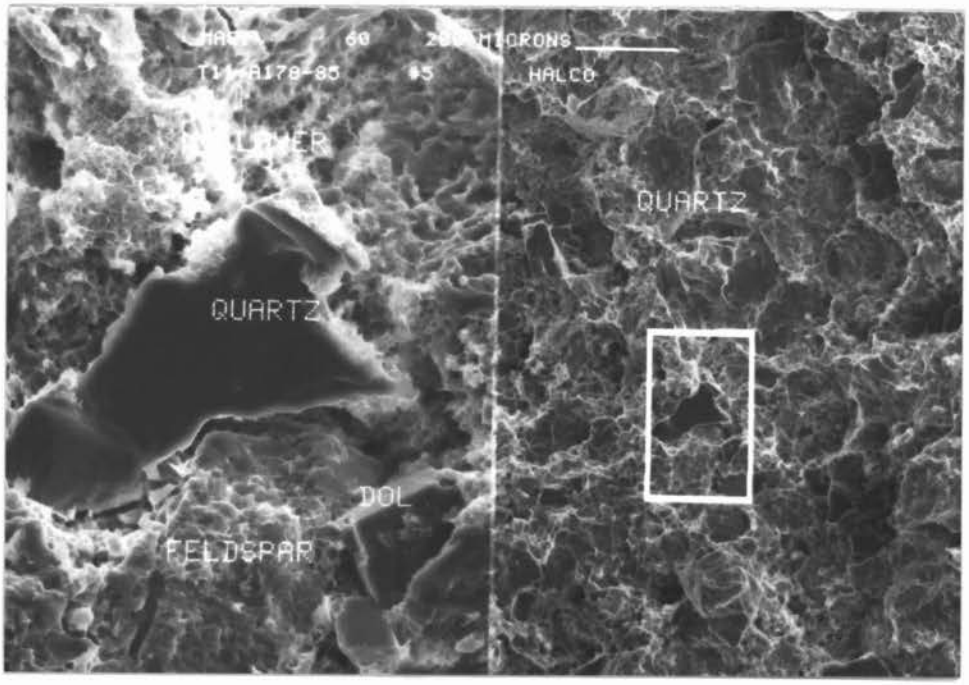

Figure No. 6; Negative No. 21805-9140; Magnification 60X and 300X

This sample is composed of fine to very fine sand size grains of quartz and feldspar. Mixed layer clay is noted in the high magnification view.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Core Sample Disposition

The core samples will be held in storage for 60 days following mailing of the report. At the end of this time, we will select representative core pieces for storage in the Core Library and discard the remainder unless we are requested to ship the cores to another location.

The selected core pieces will be in the Core Library for two years and will be considered the property of the customer. These core pieces will not be released without the permission of the customer, the originating Halliburton Engineer, or a Stimulation Engineering and Design Section Supervisor. After two years, the selected core pieces will be kept for another eight years, during this time the pieces may be used for a variety of projects.

Data Book Reference

The data presented in this report are recorded in Stimulation Engineering and Design Book No. 5789, pages 37 and 68; Analytical Book No. 5826, page 31; Analytical Book No. 5804, page 45; Analytical Book No. 5823, page 73; Analytical Book No. 5813, page 33; Analytical Book No. 5785, page 73; and Analytical Book No. 5822, page 53.

CONDITIONS AND QUALIFICATIONS

Mineralogy, Inc. will endeavor to provide accurate and reliable laboratory measurements of the samples provided by the client. The results of any x-ray diffraction, petrographic or core analysis test are necessarily influenced by the condition and selection of the samples to be analyzed. It should be recognized that geological samples are commonly heterogeneous and lack uniform properties. Mineralogical, geochemical and/or petrographic data obtained for a specific sample provides compositional data pertinent to that specific sampling location. Such "site-specific data" may fail to provide adequate characterization of the range of compositional variability possible within a given project area, thus the "projection" of these laboratory findings and values to adjoining, "untested" areas of the formation or project area is inherently risky, and exceeds the scope of the laboratory work request. Hence, Mineralogy, Inc. shall not assume any liability risk or responsibility for any loss or potential failure associated with the application of "site or sample-specific laboratory data" to "untested" areas of the formation or project area. Unless otherwise directed, the samples selected for analysis will be chosen to reflect a visually representative portion of the bulk sample submitted for analysis. Where provided, the interpretation of x-ray diffraction, petrographic or core analysis results constitutes the best geological judgment of Mineralogy, Inc., and is subject to the sampling limitations described above, and the detection limits inherent to semi-quantitative and/or qualitative mineralogical and microscopic analysis. Mineralogy, Inc. assumes no responsibility nor offers any guarantee of the productivity, suitability or performance of any oil or gas well, hydrocarbon recovery process, dimension stone, and/or ore material based upon the data or conclusions presented in this report.

This report is to only be replicated in its entirety.

Sample Retention: Samples will be stored for a period of 30 days and thereafter discarded. If additional sample storage time and/or return shipping is required, appropriate charges will be billed to the client.

Summary

Five matrix-rich conventional core plug samples from the AERA 888N-12 well within the Coalinga Field have been submitted for x-ray diffraction (XRD), thin section and scanning electron microscopy analysis. All five of the cores are classified as clay-rich, fossiliferous sandy siltstone. The siltstones are grain-supported, burrow mottled, locally ripple-bedded, fossiliferous and microporous. Detrital clay matrix is ubiquitous as a pore-filling constituent, occupying nearly all of the available intergranular spaces. The grain materials are closely spaced & exhibit common point-to-point and elongated intergranular contacts. Selected foram tests have been crushed due to burial compaction. Detrital grain materials include plagioclase feldspar & quartz silt grains, coupled with silt to sand-sized skeletal grain fragments, chert rock fragments (RFs), re-crystallized igneous RFs, organic matter particles, and glauconite pellets. Skeletal grain materials are calcareous & include scattered foram tests & fragments, echinoderm plates, and undifferentiated skeletal debris. The XRD data set indicates a mineralogy comprised of clay matrix minerals (~31-46.5%), plagioclase feldspar (11-23%), quartz (12-19%), calcite (7-16%), amorphous material (10-15%), dolomite (0-7%), k-feldspar (1-2%), and pyrite (1.5-3%). The clay mineral suite is dominated by mixed-layered illite/smectite (24-46%), together with moderate amounts of illite/mica (0.5-3%), chlorite (0-3%), and kaolinite (0-1%). The siltstone samples are microporous & are limited to small amounts of residual intergranular macroporosity and intra-particle dissolution porosity. The intergranular voids are limited to small (typically ~ 5-40 um) residual pores that are locally isolated due to the pore-filling clay matrix. The over-abundance of pore-filling detrital clay and the limited preservation of macroporosity indicates that these siltstone intervals are likely to perform as efficient permeability barriers capable of trapping hydrocarbons.

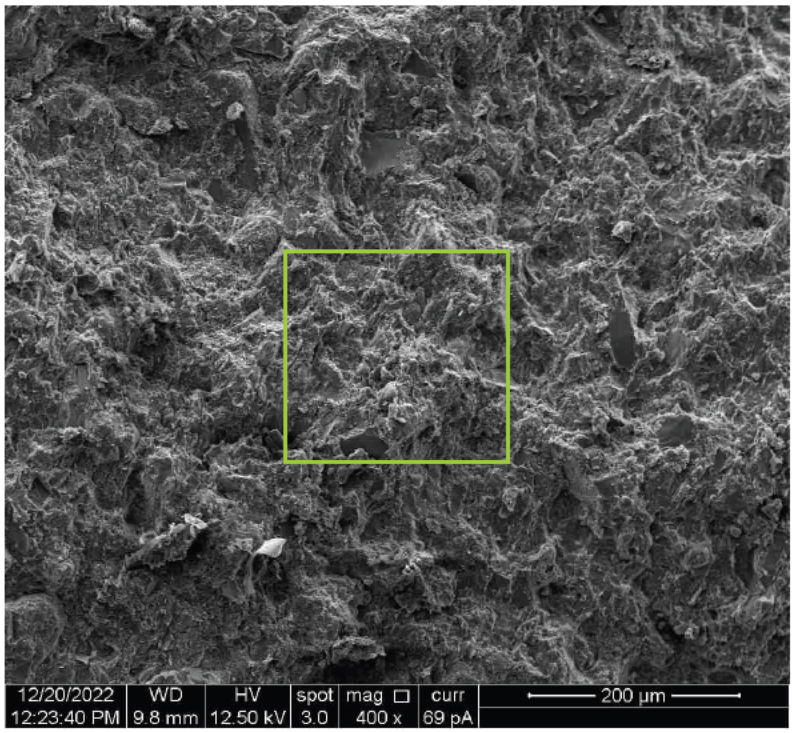
AERA

Well: 888N-12 | Field: Coalinga

8685.5 ft.

MI#22341-01 - SEM



Summary: This core sample is characterized as a non-porous, matrix-rich, fossiliferous, sandy siltstone. The siltstone is well sorted, sub-angular, and densely packed, with a mean grain diameter of ~ 0.045 mm and a maximum grain diameter of 0.82 mm. Bioturbation has obscured the original ripple-bedded fabric and has distributed densely crystallized, organic-rich detrital clay matrix throughout the intergranular pore system. Calcareous foram tests are common throughout the fabric. A few of the forams are in-filled with pore-filling clay & have withstood burial compaction, while other skeletal grains have been subjected to fragmentation & collapse. Selected forams are partially to completely replaced with dolomite cement. Minor amounts of dolomite are also present as very fine subhedral crystals of cement that are locally admixed with the pore-filling clay matrix. The detrital assemblage includes quartz (monocrystalline & polycrystalline), feldspar (plagioclase > k-feldspar), calcareous skeletal fragments (mostly foram fragments & undifferentiated skeletal debris), shale / mudstone RFs, chert RFs, igneous RFs, organic matter particles, and glauconite. The mineralogy of the siltstone is comprised of plagioclase feldspar (~19%), quartz (~12%), calcite (~12%), dolomite (~7%), pyrite (~3%), k-feldspar (~1%), amorphous material (~12%) and clay minerals (~34%) [seeTable I]. The clay mineral suite is dominated by mixed-layered illite/smectite (29%) + subordinate amounts of chlorite (2%), illite/mica (2%), and kaolinite (1%). This interval is likely to serve as an effective reservoir seal.

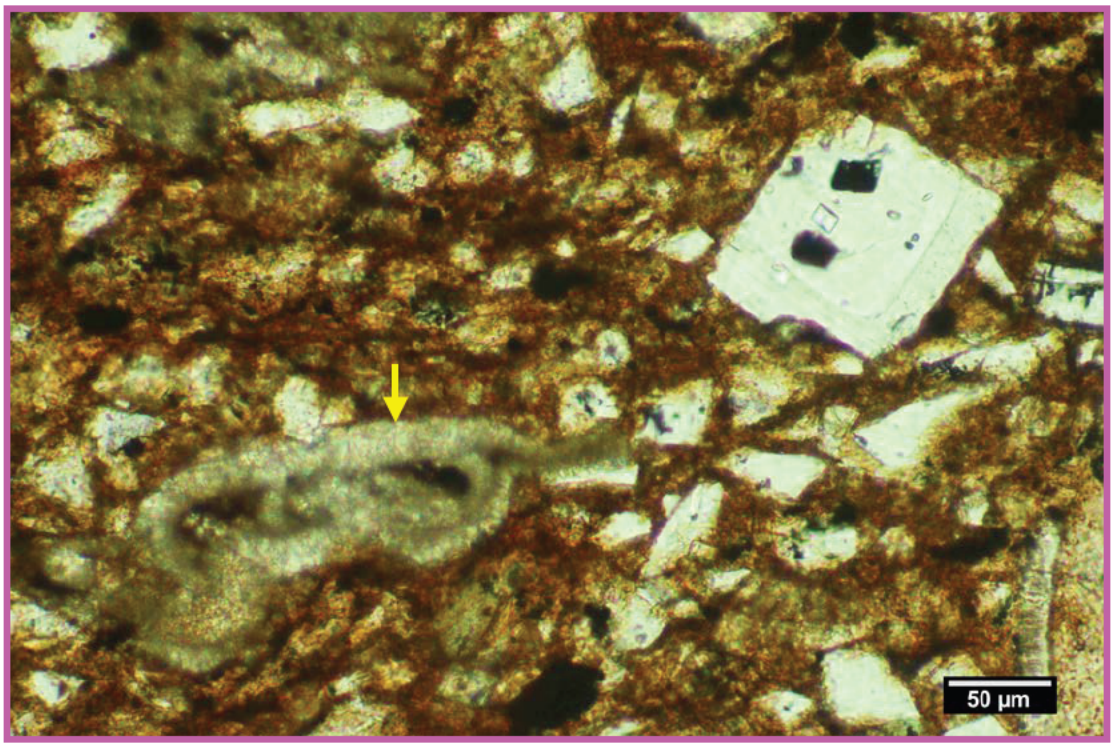
1A. Low magnification view of a non-porous, burrow-mottled, matrix-rich sandy siltstone. The highlighted area is detailed in Figure 1B.



1B. The siltstone framework is moderately to densely packed, with organic-rich detrital clay filling all of the available intergranular space. The highlighted area is detailed in Figure 1C.

8685.5 ft.; MI#22341-01

1C. Sand-sized detrital grains are present & include calcareous foraminifera (red <), quartz feldspar grains (blue <) and altered igneous rock fragments. The highlighted area is detailed in Figure 1D.

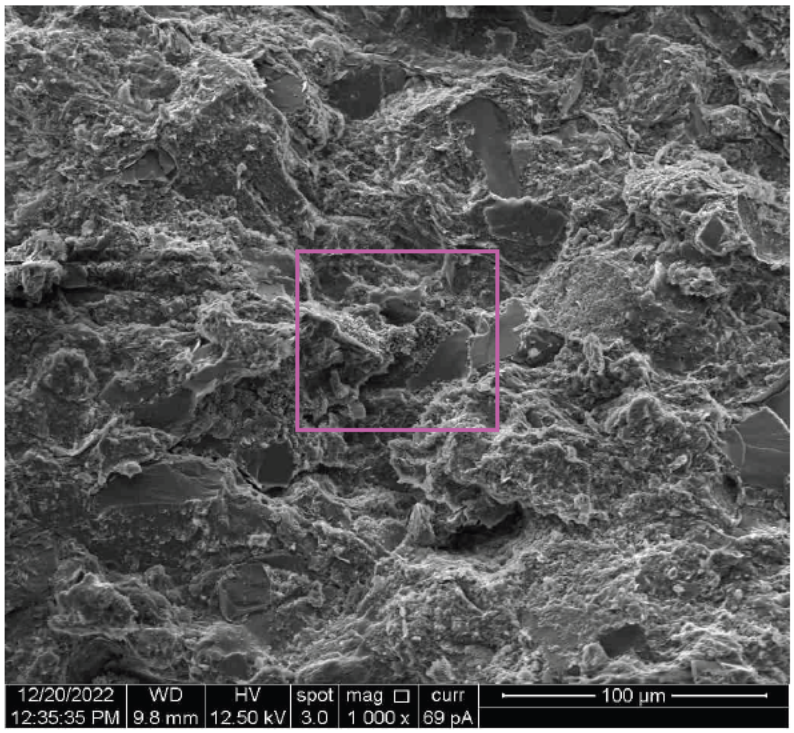
1D. The framework is densely packed and non-porous. Burial compaction has locally collapsed selected (un-cemented) foram tests (yellow <).

AERA

Well: 888N-12 | Field: Coalinga

8697.5 ft.

MI#22341-02 - SEM



Summary: This core sample is characterized as a non-porous, matrix-rich, fossiliferous, sandy siltstone. The siltstone is moderately well sorted, sub-angular, and moderately packed, with a mean grain diameter of ~ 0.04 mm and a maximum grain diameter of 1.11 mm (echinoderm skeletal fragment). Bioturbation has obscured the original ripple-bedded fabric and has serve to homogenize the sedimentary fabric. Calcareous skeletal fragments include: foram tests, rare echinoderm plates, and undifferentiated skeletal debris). Selected forams are in-filled with pore-filling clay &/or calcite spar cement. Several of the skeletal grains are crushed due to burial compaction. The detrital assemblage includes quartz (monocrystalline & polycrystalline), feldspar (plagioclase > k-feldspar), calcareous skeletal fragments, shale / mudstone RFs, chert RFs, organic matter particles, and glauconite. The mineralogy of the siltstone is comprised of plagioclase feldspar (~23%), quartz (~19%), calcite (~11%), pyrite (~3%), k-feldspar (~2%), siderite (~1%), amorphous material (~10%) and clay minerals (~31%) [seeTable I]. The clay mineral suite is dominated by mixed-layered illite/smectite (24%) + subordinate amounts of chlorite (3%), illite/mica (3%), and kaolinite (1%). The siltstone lacks inter-connected macroporosity & is likely to serve as an effective reservoir seal.

2C. A calcite spar-filled foram test (magenta <). Periodic storm events & bioturbation have influenced the grain distribution & sorting of this sandy siltstone.

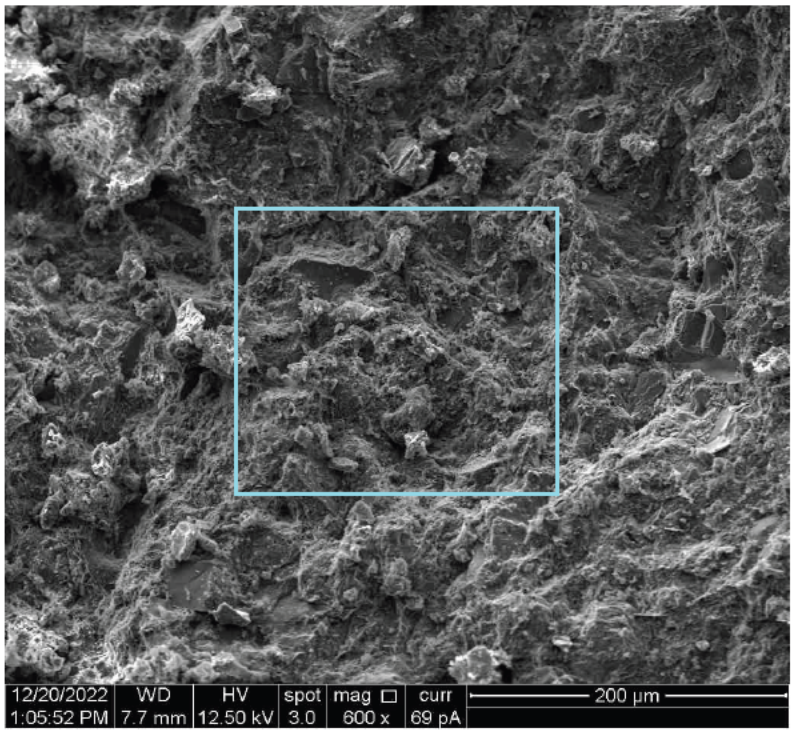
2D. Silt-sized grains of glauconite (green; yellow <) are locally present. The pore system is largely limited to intercrystalline microporosity + traces of sheltered interparticle porosity.

AERA

Well: 888N-12 | Field: Coalinga

8708.6 ft.

MI#22341-03 - SEM



Summary: This core sample is comprised of non-porous, matrix-rich, fossiliferous, sandy siltstone. The siltstone fabric is moderately well sorted, sub-angular and moderately packed. The mean grain diameter is ~ 0.035 mm and a maximum grain diameter of 1.95 mm (calcareous foram test). Bioturbation has homogenized the sedimentary fabric. Calcareous skeletal fragments include foram tests and undifferentiated skeletal debris. Selected forams are in-filled with pore-filling clay &/or calcite spar cement. The detrital grain assemblage is moderately packed and displays common point-to-point intergranular contacts. Grain varieties include: quartz (monocrystalline & polycrystalline), feldspar (plagioclase > k-feldspar), calcareous skeletal fragments, shale / mudstone RFs, chert RFs, organic matter particles, and glauconite. XRD data (see Table I) indicates a mineralogy comprised of plagioclase feldspar (~20%), quartz (~16%), calcite (~11%), pyrite (~2.5%), k-feldspar (~2%), dolomite (~2%), amorphous material (~12%) and clay minerals (~34.5%) [seeTable I]. As within the other siltstone cores evaluated from this well, the clay mineral suite is dominated by mixed-layered illite/smectite (31%) + subordinate amounts of chlorite (2%), illite/mica (1%), and traces of kaolinite (0.5%). The siltstone lacks (effective) inter-connected macroporosity & is likely to perform as a low permeance reservoir seal.

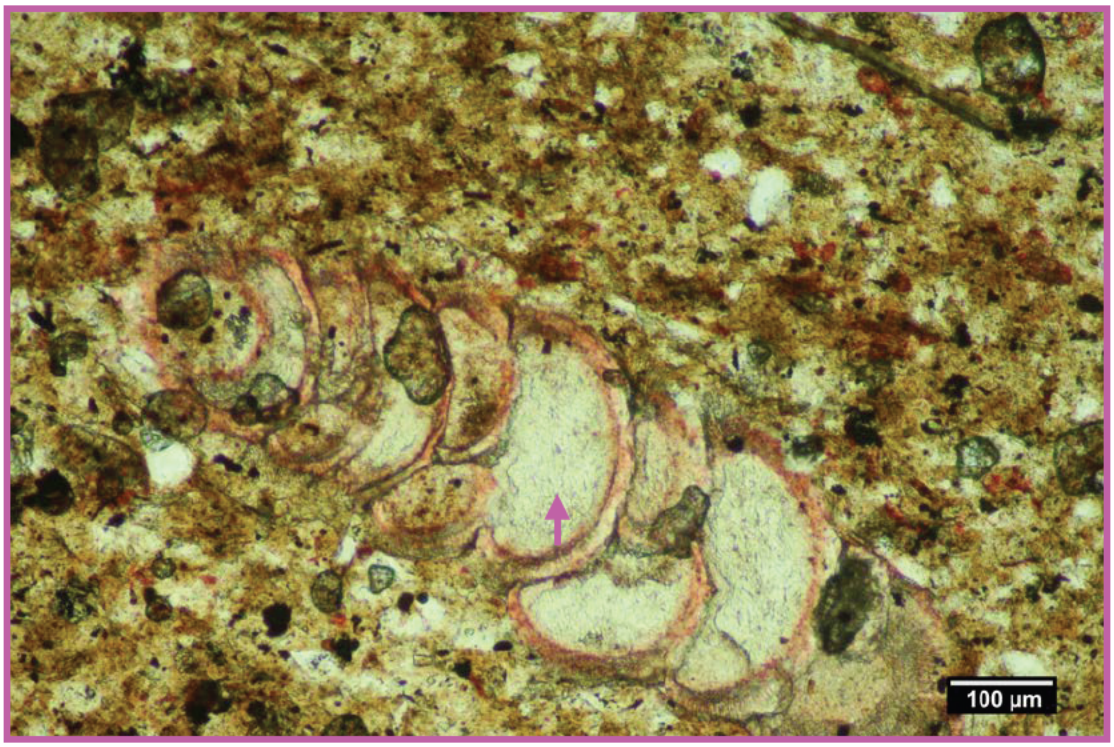
3A. The void system is limited to traces of sheltered inter-particle porosity + intercrystalline microporosity. The highlighted area is detailed in Fig, 3B.



3B This foram test is in-filled with vermicular kaolinite (blue <).The groundmass of the siltstone (red <) consists of densely bundled & compressed detrital clay.

8708.6 ft.; MI#22341-03

3C This siltstone is non-porous, matrix-rich and fossiliferous. Selected foram tests are in-filled with microporous clay matrix materials (magenta <). The highlighted area is detailed in Fig. 3D.

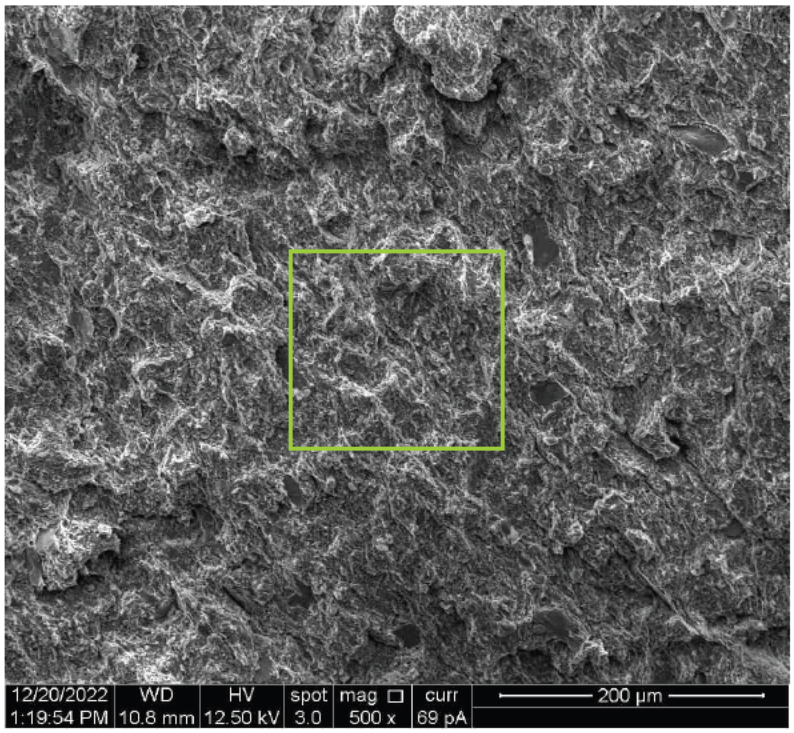
3D. All of the available intra-particle & intergranular spaces have been filled with clay matrix. The clay filling this foram test is ML illite/smectite (magenta <).

AERA

Well: 888N-12 | Field: Coalinga

8715.5 ft.

MI#22341-04 - SEM



Summary: This core sample is comprised of non-porous, organic matter & clay matrix-rich, burrow-mottled, fossiliferous, sandy siltstone. The siltstone fabric is moderately well sorted, sub-angular and moderately packed. The mean grain diameter is ~ 0.045 mm and a maximum grain diameter of 1.5 mm (re-crystallized igneous RF). The fabric is burrow-mottled & exhibits remnants of ripple-bedding. Calcareous foram tests and undifferentiated skeletal grain fragments are dispersed throughout the fabric. All of the intra-particle growth chambers of the forams in this slide are in-filled with authigenic clay matrix. The detrital grain assemblage is moderately to densely packed and displays common point-to-point & elongated intergranular contacts. Grain varieties include: quartz (monocrystalline & polycrystalline), feldspar (plagioclase > k-feldspar), calcareous skeletal fragments, shale / mudstone RFs, chert RFs, re-crystallized igneous RFs, organic matter particles, and glauconite. XRD data (see Table I) indicates a mineralogy comprised of quartz (~17%), plagioclase feldspar (~11%), calcite (~7%), pyrite (~1.5%), k-feldspar (~1%), dolomite (~1%), amorphous material (~15%) and clay minerals (~46.5%) [seeTable I]. The clay suite within this interval is limited to mixed-layered illite/smectite (46%) & traces of illite/mica (0.5%). The siltstone lacks (effective) inter-connected macroporosity & is likely to perform as a low permeance reservoir seal.

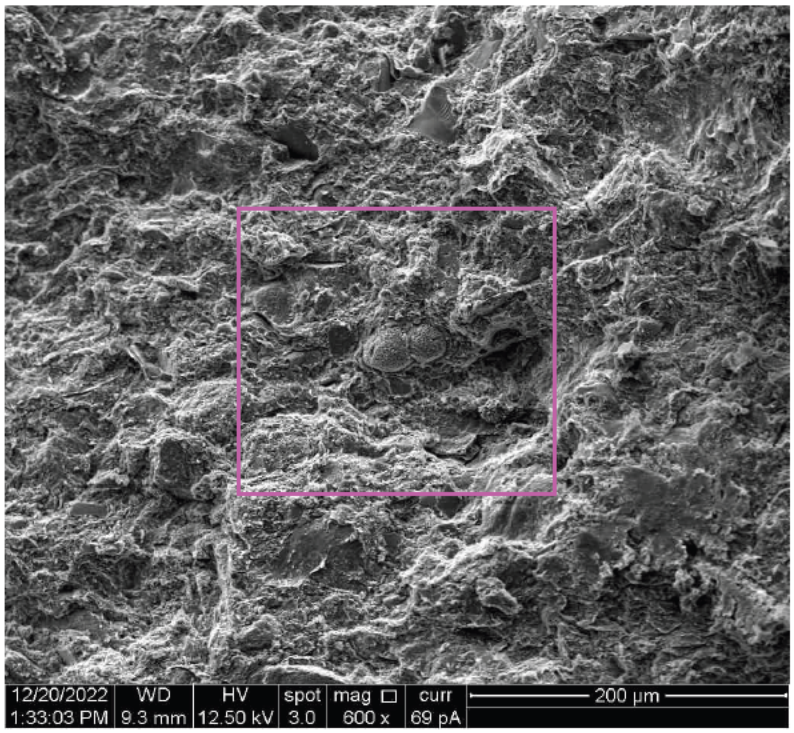
MI#22341-05 - SEM



Summary: This core sample is comprised of matrix-rich, calcareous & fossiliferous, sandy siltstone. The siltstone is moderately well sorted, sub-angular, and moderately to densely packed, with a mean grain diameter of ~ 0.045 mm and a maximum grain diameter of 0.75 mm. The siltstone fabric is ripple bedded and burrow mottled, and contains common silt-sized fragments of finely divided (& undifferentiated) skeletal grain material. Calcareous skeletal fragments include: foram grain debris, echinoderm plates, and undifferentiated skeletal fragments. Several of the skeletal grains are crushed due to burial compaction and rims of calcite spar cement are also locally present. The detrital assemblage includes quartz (monocrystalline & polycrystalline), feldspar (plagioclase > k-feldspar), calcareous skeletal fragments, shale / mudstone RFs, chert RFs, organic matter particles, and glauconite. The XRD mineralogy of the siltstone is comprised of quartz (~16.5%), calcite (~16%), plagioclase feldspar (~15%), dolomite (3%), pyrite (~2.5%), k-feldspar (~2%), amorphous material (~10%) and clay minerals (~35%) [seeTable I]. The clay mineral suite is dominated by mixed-layered illite/smectite (32%) + subordinate amounts of chlorite (1.5%), illite/mica (1%), and kaolinite (0.5%). The siltstone lacks inter-connected macroporosity & should function as an effective reservoir seal. SEM Figures 05B & 05C illustrate pore-filling authigenic mixed-layered illite/smectite clay following the dissolution of a (host) foram test.
