Notes:

depthError: Uncertainty of reported depth of the event in kilometers.

dmin: Horizontal distance from the epicenter to the nearest station (in degrees). 1 degree is approximately 111.2 kilometers. In general, the smaller this number, the more reliable is the calculated depth of the earthquake.

gap: The largest azimuthal gap between azimuthally adjacent stations (in degrees). In general, the smaller this number, the more reliable is the calculated horizontal position of the earthquake. Earthquake locations in which the azimuthal gap exceeds 180 degrees typically have large location and depth

horizontalError: Uncertainty of reported place of the event in kilometers.

km: kilometer

locationSo: The network that originally authored the reported location of this event.

mag: The magnitude for the event.

magError: Uncertainty of reported magnitude of the event. The estimated standard error of the magnitude. The uncertainty corresponds to the specific magnitude type being reported and does not take into account magnitude variations and biases between different magnitude scales. We report an "unknown" value if the contributing seismic network does not supply uncertainty estimates.

magNST: The total number of seismic stations used to calculate the magnitude for this earthquake.

magSource: Network that originally authored the reported magnitude for this event.

magType: The method or algorithm used to calculate the preferred magnitude for the event. Typical values: "Md", "Ml", "Ms", "Mw", "Me", "Mi", "Mb", "Mlg"

net: The ID of a data contributor. Identifies the network considered to be the preferred source of information for this event.

nst: The total number of seismic stations used to determine earthquake location.

rms: The root-mean-square (RMS) travel time residual, in sec, using all weights. This parameter provides a measure of the fit of the observed arrival times to the predicted arrival times for this location. Smaller numbers reflect a better fit of the data. The value is dependent on the accuracy of the velocity model used to compute the earthquake location, the quality weights assigned to the arrival time data, and the procedure used to locate the earthquake.

Appendix 2E
Seismic History Data

USGS Seismicity Data, 1950–2022, within 15 km Radius of Area of Review, Magnitude 2.0+

Notes:
depthError: Uncertainty of reported depth of the event in kilometers
dmin: Horizontal distance from the epicenter to the nearest station (in degrees). 1 degree is approximately 111.2 kilometers. In general, the smaller this number, the more reliable is the calculated depth of the earthquake
gap: The largest azimuthal gap between azimuthally adjacent stations (in degrees). In general, the smaller this number, the more reliable is the calculated horizontal position of the earthquake. Earthquake locations in which the azimuthal gap exceeds 180 degrees typically have large location and depth
horizontalError: Uncertainty of reported place of the event in kilometers.
locationSo: The network that originally authored the reported location of this event.
km: kilometer
mag: The magnitude for the event.
magError: Uncertainty of reported magnitude of the event. The estimated standard error of the magnitude. The uncertainty corresponds to the specific magnitude type being reported and does not take into account magnitude variations and biases between different magnitude scales. We report an "unknown" value if the contributing seismic network does not supply uncertainty estimates.
magNST: The total number of seismic stations used to calculate the magnitude for this earthquake.
magSource: Network that originally authored the reported magnitude for this event.
magType: The method or algorithm used to calculate the preferred magnitude for the event. Typical values: "Md", "Ml", "Ms", "Mw", "Me", "Mi", "Mb", "Mlg"
net: The ID of a data contributor. Identifies the network considered to be the preferred source of information for this event
nst: The total number of seismic stations used to determine earthquake location.
rms: The root-mean-square (RMS) travel time residual, in sec, using all weights. This parameter provides a measure of the fit of the observed arrival times to the predicted arrival times for this location. Smaller numbers reflect a better fit of the data. The value is dependent on the accuracy of the velocity model used to compute the earthquake location, the quality weights assigned to the arrival time data, and the procedure used to locate the earthquake.

Notes:
Base of Alluvium is used for the top Tulare Fm
Base of Alluvium picked using the uppermost clay of the Tulare Fm
Coordinates provided in NAD 1983 State Plane California V FIPS 0405 (US Feet)
Controls for surface generation:
1) Well picks
2) Outcrops to control surfaces
3) 2D/3D seismic data to guide surfaces in areas of low well density
4) Groundwater monitoring wells with published top of Tulare picks

Appendix 2F
Hydrologic and Hydrogeologic Information

Water Supply Wells within AOI and 1.5-mile Buffer – Database Outputs and Well Completion Reports

Legend

Water Supply Wells

- Agricultural
- Domestic
- Public
- Industrial
- Other, Unknown, Not Specified

- Area of Review
- Area of Interest
- North/South Belridge Administrative Boundary
- 1973/74 Oil Field Boundary and Aquifer Exempt Areas
- Tulare Formation Aquifer Exemption Area
- Section
- Township

Notes:

* Indicates wells not within the internal databse of the Water Resources Management group at Aera Energy LLC. These wells were identified, based on operator knowledge, as mislocated and likely not within the Area of Interest, destroyed/not operable, or cathodic protection wells (i.e., not water supply wells). These wells were retained here due to the lack of publicly available records to confirm the well status, type, or location independent of operator records.
Wells WCR0227323 and WCR0273966 are located outside of the 1.5 mile buffer area.

N

0 1.5 Miles

Water Well Locations Within 1.5 miles of Area of Interest

Depths and distances provided in feet (ft)
Latitude/Longitude provided in Decimal Degrees
* Indicates wells not within the Water Resources Management group at Aera Energy LLC internal database, which includes records from California Geologic Energy Management Division (CalGEM), United States Geological Survey (USGS), the California Department of Water Resources (DWR), GeoTracker Groundwater Ambient Monitoring and Assessment (GAMA), and the Kern County Environmental Health Well Permit online databases in addition to their own internal records. These wells were identified, based on operator knowledge, as mislocated and likely not within the Area of Interest, destroyed/ not operable, or cathodic protection wells (i.e., not water supply wells). These wells were not included on Figure 2.7-9, but retained in this appendix due to the lack of publicly available records to confirm the well status, type, or location independent of Aera's internal records.
- Well information and location was not verified in the field and could not be confirmed with water supply districts.

Tidewater Associated Oil Co.

Carneros Pump Station. well #1.

1 first record of well 4-11-27 — well has not been used much in last 3 years. approximately 675 ft deep, 400 ft to water.

4-25-27

Run air compressor 145 R.P.M. and could only hold 50 lbs pressure at tank. pumped about 1 gal. in 45 minutes.

4-30-27

lowered nozzle to 611 ft.

5-1-27

tested out of well with air compressor 100 R.P.M pumped 12.8 gpm 768 gal/hr = 576 bbls/day at 125 R.P.M. pumped 22.054 gpm 1323 gal/hr = 1000 bbls/day at 100 R.P.M. air pressure 87 lbs @ 125 R.P.M. air pressure 90 lbs.

6-7-29

sounded 395 ft to water

3-4-32

sounded 395 ft to water, well 602 ft deep.

10-4-32

395 ft to water, 660 ft 7 pipe in well.

5-31-33

396 ft to water

27/20-34P1 5/1

27/20-34P1

5-30-34

393 ft to water approximately 537 ft sup.

395 ft to top of water

6-4-27

lowered air line nozzle to 589 ft. which brings 2½" tail pipe below nozzle 4 ft 76 bottom with bailer no improvement in amount of water pumped.

2-12-28

ran 12X14X12 L.L.D.G. compressor for 2 hrs at 88 R.P.M. and pumped 37 (25.9 gpm) bbls/hr = 884 bbls in 24 hrs — ran it 1 hr at 58 RPM and pumped 32 (22.4 gpm) bbls/hr = 768 bbls in 24 hrs. Air pressure at 88 RPM - 94 lbs at 55 RPM 89 lbs.

27/20-34P2

27/20-34P2

6-24-28

7½ x 7½ x 9" air compressor running at 100 RPM pumped 120 gpm 100 bbls/hr into tk 3 tank.

4-10-29

7½" x 7½" x 9" air compressor running at 100 R.P.M. pumped 5" of water into tk 3 tank in 6½ hrs. = 672 bbls in 24 hrs. = 19.6 gpm

6-6-29

395' to water

2-9-32

7½ x 7½ x 9" giant air compressor at 113 RPM 85 lbs pressure pumped 28 bbls/hr = 672 [illegible] = 19.6 gpm

5-26-33

well producing 18.2 gpm 26 bbls/hr. with Leed Giant - Ingersoll Gordon Compressor running at 64 R.P.M. well producing 12.2 gpm 17½ bbls/hr with Leed Giant compressor at 113 RPM

5-30-34

Sounded well to water 399' approx. 4½ 588' lap

D-log in well log file.

12-12-51

sanded up - pulled and installed new cups 400'0" of 3" tubing

2-12-52

total depth 460'0" - bottom ring [illegible] 455.30 ft

tubing 435.83 ft.

2-25-54

437.85 ft. of tubing in hole.

D-log for this well can be obtained from Production Dept. in Oil City.

Chem Acid. 1954 - in file.

17/20-34R

[illegible]

Water — 17/20-34R

[illegible] 20 years and [illegible]

Santa Fe [illegible]

[illegible] Bakersfield [illegible]

spent a lot [illegible] Bakersfield [illegible] San

Francisco thought [illegible] well [illegible] Water is piped from Semitropic

well field. Also some Edison Mapes [illegible]

water [illegible] Standard station but [illegible]

cages no well drilled. May be [illegible]

typed the [illegible] [illegible] well

about known.

WATER WELL DRILLERS REPORT

(Sections 7076, 7077, 7078, Water Code)

STATE OF CALIFORNIA

Do Not Fill In
No 9582
State Well No.____
Other Well No. 27S-20E-6

Sec 6 T 27S R 20E MDB&M

(1) OWNER:

Name

Address

(2) LOCATION OF WELL:

County Kern Owner's number, if any— 55-3

R. F. D. or Street No. 800 feet E of Sec 6 T. 27 R 20. North Side of Highway 466 Between Lerdo Canal & Friant Kern Canal

(3) TYPE OF WORK (*check*):

New well ☒ Deepening ☐ Reconditioning ☐ Abandon ☐

If abandonment, describe material and procedure in Item 11.

(4) PROPOSED USE (*check*):

Domestic ☐ Industrial ☐ Municipal ☐
Irrigation ☒ Test Well ☐ Other ☐

(5) EQUIPMENT:

Rotary ☒
Cable ☐
Dug Well ☐

(6) CASING INSTALLED:

SINGLE ☒ DOUBLE ☐

From ft.	to ft.	Diam.	Gage or Wall
0	800	16"	1/4"

Type and size of shoe or well ring —

Describe joint Bell end

If gravel packed

Diameter of Bore	from ft.	to ft.
27½	0	800

Size of gravel 3/16 to 3/8

(7) PERFORATIONS:

Type of perforator used Shop perforated

Size of perforations 1½ in., length, by 5/32 in.

From ft.	to ft.	Perf. per row	Rows per ft.

(8) CONSTRUCTION:

Was a surface sanitary seal provided? ☒ Yes ☐ No To what depth 12 ft.

Were any strata sealed against pollution? ☐ Yes ☒ No If yes, note depth of strata

From ft.	to ft.

Method of Sealing

(9) WATER LEVELS:

Depth at which water was first found 230 ft.
Standing level before perforating — ft.
Standing level after perforating — ft.

(10) WELL TESTS: S. A. Camp Pump Co.

Was a pump test made? ☒ Yes ☐ No If yes, by whom?

Yield: 2600 gal./min. with 48 ft. draw down after 40½ hrs.

Temperature of water Was a chemical analysis made? ☐ Yes ☐ No

Was electric log made of well? ☐ Yes ☐ No

(11) WELL LOG:

Total depth 800 ft. Depth of completed well 800 ft.

Formation: *Describe by color, character, size of material, and structure.*

Sensitivity Analyses and Supplemental Files

Geochemical Model Sensitivity Analyses

Ion Activity Model Selection

Geochemical modeling software packages use databases of laboratory-generated thermodynamic data to calculate mineral solubility relative to aqueous solutions. The Lawrence-Livermore National Laboratory database (LLNL.dat) contains the most robust assemblage of thermodynamic information for the mineral system comprising the target injection unit and was therefore used for this evaluation. This database includes thermodynamic data appropriate for the pressures and temperatures applicable to the target injection zone.

TDS concentrations in 64 Zone Sandstone formation waters are categorized as brackish to highly saline. As such, the Pitzer database (pitzer.dat), which utilizes the Pitzer equations as the ion activity model in the calculations [Pitzer, 1973], may be a more appropriate database to model waters of high salinity. Multiple carbon capture, utilization, and storage (CCUS) studies have demonstrated the ability of the Pitzer ion activity model to successfully replicate laboratory-derived mineral solubility constants in highly saline brines, whereas calculations completed using the extended Debye-Hückel ion activity model (the model utilized in LLNL.dat) could not replicate experimental results [Dethlefsen and Haase, 2011; Tremosa et al., 2013]. However, the Pitzer database contains limited solid phase thermodynamic information and does not include thermodynamic information for the majority of minerals present in the target injection zone. An expanded Pitzer database was produced for the Yucca Mountain Project by Sandia National Laboratory and reformatted to the PHREEQC format by Quintessa [Benbow et al., 2008]. Geochemical modeling in PHREEQC was completed using both the LLNL database and the expanded Pitzer database to evaluate sensitivity of model results to the selection of the ion activity model.

The LLNL database and the expanded Pitzer database contain appropriate thermodynamic information for most minerals present in the system except for glauconite. Glauconite (an authigenic iron-potassium phyllosilicate mineral in the clay/mica family) was observed in petrographic analyses and plays a role in the fate of important cementing-building aqueous components like iron, aluminum, and silica. The LLNL database was modified to include thermodynamic information for this mineral from Blanc et al. [2015]. The architecture of the expanded Pitzer database does not allow for the inclusion of some additional minerals; therefore, glauconite was not addressed using this database. Of note, the expanded Pitzer database is unable to incorporate aqueous redox pairs. As a result, aqueous ferric (Fe^{3+}) iron and sulfide are not considered in Pitzer calculations. Modeling efforts in PHREEQC utilized the LLNL thermodynamic database and the expanded Pitzer thermodynamic database, with the LLNL database modified to include glauconite. The expanded Pitzer database is not available in the Geochemists Workbench™ (GWB) format, and thus, GWB modeling was completed using only the modified LLNL database.

Appendix 2G Tables 1 and 2 provide results for the LLNL thermodynamic database model runs and the expanded Pitzer thermodynamic database model runs for aqueous components and solid-phase components respectively. A comparison between the results of each approach is provided as the sensitivity difference column in each table.

Comparison of results from the LLNL database and the expanded Pitzer database indicate that differences for most parameters are relatively minor, suggesting a limited influence of ion activity model selection. Of note, aqueous results for iron, sodium, alkalinity, and potassium differ appreciably, although the direction of these changes relative to the initial composition are consistent (e.g., alkalinity significantly increases in model outputs relative to initial composition for both methods). The discrepancies between aqueous iron and sulfate results were likely a byproduct of the expanded Pitzer database's inability to assess redox reactions. It stands to reason that LLNL model results for aqueous iron and sulfate are more realistic. Differences in the treatment of sodium, potassium, and chloride between the two ion activity models are well documented [Dethlefsen and Haase, 2011; Tremosa et al., 2013].

Initial saturation index (SI) calculations differ between the two approaches as a function of each ion activity model's method of calculating ion activity coefficients. Comparison of LLNL and Pitzer results revealed minor differences in modeled solid-phase delta outputs; however, the modeled minerals should react in the same direction (i.e., precipitate or dissolve) regardless of database selection. This observation, combined with the sensitivity analysis results for the aqueous phase, supports the conclusion that both databases provide reasonable predictions of mineral reactivity.

Reaction pathway result comparisons are presented in **Appendix 2G Table 3**. Reaction pathway modeling calculations performed in PHREEQC using the LLNL and expanded Pitzer databases yielded different values for SIs; however, both models suggested identical trends in predicted SI changes relative to present conditions. The most significant difference between the two databases was observed with calculated SIs for kaolinite and dolomite. These minerals reacted in the same direction following injectate introduction (decrease in SI relative to current state), but a difference was observed between the initial pre-injection SIs. Dolomite in LLNL database model runs was initially supersaturated and shifted to undersaturated following injection, compared to dolomite in Pitzer database model runs which was initially very supersaturated and shifted to less supersaturated. Likewise, kaolinite in LLNL database model runs was initially undersaturated and became even more undersaturated following injection interaction, and kaolinite in Pitzer model runs was initially supersaturated and shifted to less supersaturated (**Appendix 2G Table 3**). Comparison between equilibrium models indicated that predicted mineral mass changes for these minerals from the two databases yield a sensitivity difference of 0.001 mol/L for dolomite and 0.394 mol/L for kaolinite (**Appendix 2G Table 2**). These values were not considered consequential enough to warrant further sensitivity testing using the expanded Pitzer database.

Pressure-Temperature Conditions

Sensitivity analyses were performed using the geochemical modeling initial inputs and general methods described in **Section 3.3.2** to evaluate the potential for geochemical pathway changes resulting from modifying pressure/temperature conditions through the continual addition of injectate gas. Injectate gas temperature is predicted to be 35°C at the time of injection. The continual addition of injectate into the hotter (112.8°C) subsurface is expected to cool the surrounding injection zone formation, and thus potentially alter thermodynamic relationships and kinetic rates. Additionally, continued injection of gas into the target injection zone zone is expected

to increase total pressure within the system. The maximum anticipated pressure resulting from CO_2 injection is approximately 80% of the 4,200 psi discovery pressure (i.e., a maximum of 3,360 psi or 229 atm).

Sensitivity analyses were performed by first running the base case model simulation using model inputs described in **Section 3.3.2.1**. Base case inputs were used to generate model outputs for each of the multiple modeling approaches (thermodynamic reaction pathway modeling, thermodynamic equilibrium modeling, and kinetic reaction pathway modeling). These model outputs represent an intermediate step in pressure-temperature sensitivity modeling which assumes that the system reaches full thermodynamic equilibrium in the case of thermodynamic models and that kinetically controlled geochemical reactions occur over the defined 50-year time period in the case of kinetic modeling. These base case model outputs are then provided as initial inputs for a second model run in which the adjusted pressure-temperature values are used. The iterative modeling process assesses aqueous geochemical and mineral mass changes resulting from an initial period of equilibration associated with the beginning of gas injection which then is subjected to modified pressure-temperature conditions and allowed to continue geochemical reactions.

Two sensitivity model runs were completed to simulate cooling of the surrounding reservoir system at temperatures of both 35°C (expected temperature of injectate gas) and 90°C (lower than the initial system temperature by approximately 30% of the difference between the current formation and injectate temperatures) while maintaining the anticipated high pressure of 229 atm. The sensitivity analyses are intended to assess the geochemical impact of induced pressure-temperature changes on the system as a result of the injection process. Sensitivity analysis conditions are not believed to be fully representative of future conditions; rather, results bracket the plausible maximum impacts of pressure-temperature changes induced by future injection.

The sensitivity analysis for the equilibrium model was conducted in PHREEQC using only the LLNL thermodynamic database, as results of the LLNL and expanded Pitzer calculations were deemed to be sufficiently comparable. Sensitivity testing of reaction pathway modeling was conducted in PHREEQC using the LLNL database and GWB React module using the LLNL database incorporating identical mineral kinetic values as the base case modeling effort. React models were set to run for 50 years using base case conditions during the intermediate step, and an additional 50 years using adjusted pressure-temperature conditions during the final step.

Results of sensitivity runs were compared to initial conditions (base case model inputs) to evaluate predicted changes relative to pre-injection conditions. Sensitivity analysis results for equilibrium modeling are provided in **Appendix 2G Table 4** (aqueous concentrations) and **Table 5** (mineralogy). Results for reaction pathway modeling using PHREEQC are provided in **Appendix 2G Table 6**. Results tables display initial conditions (base case model inputs), intermediate step inputs (base case model outputs), and sensitivity model outputs. Delta columns reflect the difference between sensitivity model outputs and initial conditions and the difference between sensitivity model outputs and base case model outputs.

Sensitivity analysis equilibrium modeling results are interpreted as the final model outputs relative to initial (pre-injection) conditions compared to the base case model outputs relative to initial

conditions. Results indicated that nearly every reaction identified in base case modeling will continue to proceed through changing pressure-temperature conditions, with the exception of a potential shift to dissolution of potassium feldspar under cooler conditions and precipitation of the mineral dawsonite ($NaAlCO_3(OH)_2$) under both temperature conditions (**Table 5**). Apart from potassium feldspar and dawsonite, the mineral mass fluctuations are predicted to continue in the same direction as base case modeling results. Aqueous concentration changes maintained the same direction for all analytes except for iron (only in the case of the 35°C condition) and boron (**Table 4**). The directions of predicted changes in aqueous parameter concentrations following sensitivity runs relative to the base case remained largely consistent, indicating that the same mechanisms and reactions would continue to occur during the second iteration of the sensitivity modeling process, only at different rates and scales. Sensitivity analysis conditions resulted in increased rates of aqueous concentration and mineral mass changes. Nonetheless, sensitivity conditions predicted minor changes in individual mineral masses compared to the results of the base case.

The sensitivity analyses for reaction pathway modeling revealed a similar observation. PHREEQC-calculated SIs for both sensitivity analysis conditions maintained the same direction as the base case scenario for most minerals, with exceptions of potassium feldspar at 35°C and kaolinite and dawsonite at both temperatures (**Table 6**). Results suggest that the precipitation of dawsonite and kaolinite would be favorable as conditions change due to the impact of gas injection. This predicted kaolinite precipitation may occur at the expense of feldspar minerals albite and potassium feldspar, as both minerals are predicted to remain undersaturated in sensitivity conditions and both minerals are predicted to dissolve in sensitivity modeling with the exception of potassium feldspar in 35°C conditions. The formation of kaolinite at the expense of feldspar is known to commonly occur during diagenesis. The precipitation of dawsonite may also occur at the expense of feldspar minerals, as predicted from geochemical modeling evaluations of high-salinity sandstone systems following carbon injection activities [Johnson et al., 2001; Rochelle et al., 2004].

Kinetic reaction pathway model outputs for the high-pressure, 35°C sensitivity conditions are provided as **Appendix 2G Figures 1 through 5**. Model outputs for the high-pressure, 90°C sensitivity conditions are provided as **Appendix 2G Figures 6 through 10**. Generally, kinetic reaction pathway modeling using sensitivity analysis conditions also predicted similar reactions would occur at higher rates. Sensitivity modeling using lower temperature (35°C) conditions predicted a total mineral mass decrease of 41 kilograms per cubic meter (kg/m^3) relative to the base case results (**Figure 4**). This predicted mineral mass decrease would result in an additional porosity increase of 1.6% (i.e., an increase of 0.016 relative to the 0.13 total porosity value) over the second model iteration at changed pressure-temperature conditions (**Figure 5**). The predicted mineral mass decrease using higher temperature (90°C) sensitivity conditions was 46 kg/m^3 (**Figure 9**), which corresponds to an additional porosity increase of 1.8% (i.e., an increase of 0.018 relative to the 0.13 total porosity value) over the second the second model iteration at changed pressure-temperature conditions (**Figure 10**). Under both sensitivity analysis conditions, the rate of porosity increase was predicted to decline after approximately 40 years, as seen by the curves partially leveling off (**Figures 5** and **10**).

Generally, the sensitivity analyses indicated that predicted mineral reactions and aqueous/mineral changes would maintain the same directions as in the base case effort, but these changes are predicted to increase in magnitude during the second model iteration under sensitivity analysis conditions. Quartz is an exception to this conclusion, as quartz was predicted to dissolve under sensitivity conditions in kinetic reaction pathway models despite thermodynamic sensitivity models predicting quartz precipitation. Dawsonite, a mineral which was not expected to precipitate during the base case model run, was predicted to precipitate, potentially at the expense of potassium feldspar and albite. Kinetic modeling predicted that total porosity (0.13) would increase by 0.017 (0.0015 during the base case model iteration and 0.0156 within the sensitivity model iteration) under high pressure/35°C sensitivity conditions, and by 0.019 (0.0015 during the base case model iteration and 0.0177 within the sensitivity model iteration) under high pressure/90°C sensitivity conditions. Thus, the porosity change of 1.9 porosity units constitutes the maximum expected porosity change associated with sensitivity modeling of gas injection.

Appendix 2G
Geochemistry Supporting Data

Predicted Geochemical Reactions Following Injectate Gas Interaction

Predicted Geochemical Reactions Following Injectate Gas Interaction

- CO_2 dissolution into formation water

$$CO_2(g) + H_2O \rightarrow H_2CO_3$$

- Carbonic acid dissolution into bicarbonate

$$H_2CO_3 \rightarrow H^+ + HCO_3^-$$

- Bicarbonate dissociation into carbonate

$$HCO_3^- \rightarrow H^+ + CO_3^{2-}$$

- Dissolution of K-feldspar

$$KAlSi_3O_8 + 8\,H2O \rightarrow K^+ + Al(OH)_4^- + 3\,H_4SiO_4$$

- Dissolution of plagioclase feldspar

$$NaAlSi_3O_8 + 8H_2O \rightarrow Na^+ + Al(OH)_4^- + 3\,H_4SiO_4$$

- Dissolution of illite

$$K_{0.6}Mg_{0.25}Al_{2.3}Si_{3.5}O_{10}(OH)_2 + 11.2\,H_2O \rightarrow 0.6\,K^+ + 0.25\,Mg^{2+} + 2.3\,Al(OH)_4^- + 3.5\,H_4SiO_4 + 1.2\,H^+$$

- Dissolution of smectite

$$Ca_{0.25}Na_{0.1}K_{0.2}Fe_{0.7}Mg_{1.15}Al_{1.25}Si_{3.5}O_{10}(OH)_2 + 8\,H^+ \rightarrow 0.25\,Ca^{2+}\,0.1\,Na^+ + 0.2\,Fe^{3+} + 0.5\,Fe^{2+} + 0.2\,K^+ + 1.15\,Mg^{2+} + 1.25\,Al^{3+} + 3.5\,SiO_2 + 5\,H_2O$$

- Dissolution of kaolinite

$$Al_2Si_2O_5(OH)_4 + 6\,H^+ \rightarrow H_2O + 2\,H_4SiO_4 + 2\,Al^{3+}$$

- Dissolution of carbonate (as calcite) cements

$$CaCO_3 \rightarrow CO_3^{2-} + Ca^{2+}$$

- Precipitation of quartz cements

$$H_4SiO_4 \rightarrow SiO_2 + 2\,H_2O$$

- Potential precipitation of kaolinite

$$H_2O + 2\,H_4SiO_4 + 2\,Al^{3+} \rightarrow Al_2Si_2O_5(OH)_4 + 6\,H^+$$

- Reprecipitation of carbonate (as calcite) cements

$$CO_3^{2-} + Ca^{2+} \rightarrow CaCO_3$$

- Precipitation of Fe-oxyhydroxide (as hematite) minerals

$$2\,Fe^{3+} + 3\,H_2O \rightarrow Fe_2O_3$$

- Precipitation of calcium aluminosilicate (as laumontite) minerals

$$1\,Ca^{2+} + 2\,Al^{3+} + 8\,H_2O + 4\,SiO_2 \rightarrow CaAl_2Si_4O_{12} \cdot 4\,H_2O + 8\,H^+$$

- Potential precipitation of dawsonite (under sensitivity pressure-temperature conditions)

$$Al^{3+} + HCO_3^- + Na^+ + 2H_2O \rightarrow NaAlCO_3(OH)_2 + 3H^+$$

Class VI CO_2 Injection and Monitoring Well Construction Details

Contents

Well-Specific Construction Details for the following wells:

- **New Drill Injection Well**
- **Injection Well 27R-27N**
- **Injection Well 55-26N**
- **Injection Well 64-35N**
- **Injection Well 9-1N**
- **Injection Well 64-27N**
- **Monitoring Well 1-28N**
- **Monitoring Well 25-26N**
- **Monitoring Well 27-1N**
- **Monitoring Well 35X-27N**
- **Monitoring Well 39-26N**

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: New Drill Injection Well
API No. N/A

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
See "Table 5-2: New Drill Wells to be Constructed as Co2 Injection Wells" in Section 5 of the Application Narrative.

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. This is a new drill well drilled and completed as an EPA Class VI CO_2 injection well.

1.1.1 Rationale for a Casing-Liner Well Design

The injection zone (64 Zone Sandstone) has been on oil and gas production for decades, and the reservoir pressure has been depleted from original at over 4,000 pounds per square inch (psi), to approximately 700 psi. The reduction in pressure impacts the cementing process where circulating cement to surface is a requirement for EPA Class IV wells. Cement slurry densities normally used for zonal isolation range from 16 pounds per gallon (ppg) to as low as 12.5 ppg for extended yield slurry designs. Attempting to set and cement casing at the base of the 64 Zone Sandstone will likely result in fluid losses to the formation and not bring cement to surface. Therefore, long string casing will be set and cemented at the base of the Lower Santos shale (the primary confining zone), which should bring cement to surface (40 CFR 146.86(b)(3)).

2. WELL DESIGN

2.1 Directional

The well will be drilled as a vertical well. Directional surveys will be taken as the well is drilled.

2.2 Underground Sources of Drinking Water

The Tulare formation is the only potential USDW but has an approved Aquifer Exemption.

2.3 Tubing and Packer

Injection will be through tubing and a packer per 40 CFR 146.86(c)(2). Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative, Attachment K,** and **Table 10** and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the casing is run and cemented.

The tubing size was selected based on the proposed injection rate, composition, and reservoir conditions. The fluid flow model PROSPER[1] was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has Pressure-Volume-Temperature (PVT) correlations that have been validated for CO_2 injection with a wide range of impurities.

The tubing wall thickness was selected to account for corrosion wall loss including upset conditions for the selected grade. Corrosion wall loss estimates were determined using OLI,[2] an industry standard commercial thermodynamic corrosion analysis program for aqueous systems.

2.4 Proposed Perforations

Proposed perforations will be selected based on the new well location.

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	TBD	TBD
64 Zone Sandstone	TBD	TBD

ft: feet

2.5 Maximum Surface Pressures and Mechanical Integrity

The operating injection pressure will depend on the reservoir pressure, the properties of the injected fluid, the wellbore friction, and the rate. PROSPER was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has PVT correlations that have been validated for CO_2 injection with a wide range of impurities.

The annulus pressure will be maintained at a pressure higher than the tubing injection pressure as required per CFR 146.88(c). The design pressure loads on the injection tubing and tubing by casing annulus are as follows:

- Maximum tubing injection pressure 2,800 psi
- Maximum annulus pressure 2,900 psi
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

[1] https://www.petex.com
[2] https://www.olisystems.com/

The maximum tubing injection and shut-in pressures are based on PROSPER flow assurance modeling. The maximum annulus pressure is higher than the maximum injection pressure as required per CFR 146.88(c).

After each casing and liner is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal or greater than the design pressure for that component to demonstrate mechanical integrity.

2.6 Injection Well Casing, Liner, and Tubing Design

The casings, liner, and tubing have been designed to withstand all expected loads during the life of the well including the maximum injection and annulus pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and **Attachment K** were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the injection casing, liner, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40

2.6.1 Design Analysis Results without Corrosion

The long string casing, liner, and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the dictating design loads and the design results for nominal wall thickness casing, liner, and tubing are included in **Table 3**, **Table 4**, **Table 5**, and **Table 6**. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 7-inch Injection Casing Nominal Wall Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.36	–	>3	–	2.53
3,950 psi Shut-in tubing pressure with methane to surface	1.74	–	2.89	–	1.89

SF: safety factor

Table 4: 7-inch Injection Casing Nominal Wall Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	1.96	–	>3	–	2.09

3,950 psi Shut-in tubing pressure with methane to surface	1.97	–	2.40	–	1.98

2.6.2 Design Analysis Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing, inner liner, and tubing with respective remaining body wall (RBW) estimates are included in **Table 7**, **Table 8**, and **Table 9**, respectively. All safety factors exceed the design factors at the end of the injection phase.

Table 7: 7-inch Injection Casing 78.8% RBW Design Results Section 2

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: 27R-27N Injection Well
API No.: 0402929616

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
35° 33’ 2.4280” N, 119° 48’ 28.6103” W

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 injection well. The well will be worked over and recompleted as an EPA Class VI injection well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1942. The surface casing as shown in **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing, long-string casing, and liner details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 Directional

The well was drilled as a vertical well. The directional surveys are included in **Table 11**.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

Injection will be through tubing and a packer per 40 CFR 146.86(c)(2). Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative, Attachment K,** and **Table 10**, respectively and were selected to ensure compatibility with the injected and reservoir fluids as required by 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected based on the proposed injection rate, composition, and reservoir conditions. The fluid flow model PROSPER[1] was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has Pressure-Volume-Temperature (PVT) correlations that have been validated for CO_2 injection with a wide range of impurities.

The tubing wall thickness was selected to account for corrosion wall loss including upset conditions for the selected grade. Corrosion wall loss estimates were determined using OLI,[2] an industry standard commercial thermodynamic corrosion analysis program for aqueous systems.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	7,713	7,775
64 Zone Sandstone	7,825	8,025

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The operating injection pressure will depend on the reservoir pressure, the properties of the injected fluid, the wellbore friction, and the rate. PROSPER was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has Pressure-Volume-Temperature (PVT) correlations that have been validated for CO_2 injection with a wide range of impurities.

The annulus pressure will be maintained at a pressure higher than the tubing injection pressure as required by CFR 146.88(c). The design pressure loads on the injection tubing and tubing by casing annulus are as follows:

- Maximum tubing injection pressure 2,800 pounds per square inch (psi)
- Maximum annulus pressure 2,900 psi
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

The maximum tubing injection and shut-in pressures are based on PROSPER flow assurance modeling. The maximum annulus pressure is higher than the maximum injection pressure as required by CFR 146.88(c).

After each casing and liner is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal or greater than the design pressure for that component to demonstrate mechanical integrity.

[2] https://olisystems.com

2.7 Injection Well Casing, Liner, and Tubing Design

The new long string inner casing, inner liner, and tubing have been designed to withstand all expected loads during the life of the well including the maximum injection and annulus pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and **Attachment K** were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow wetted lower part of the inner casing, inner liner, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40

1. VME Criterion (YS derated for temperature) 2. API Minimum Internal Yield Pressure 3. API (Tension adjusted) Collapse 4. API Pipe Body Yield Strength API: American Petroleum Institute VME: Von Mises Equivalent YS: Yield Strength		

2.7.1 Design Results without Corrosion

The new long-string inner casing, inner liner, and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the design loads and the design results for the inner casing, inner liner, and tubing are included in **Table 3** , **Table 4**, **Table 5**, and **Table 6**, respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: 55-26N Injection Well
API No.: 0402935057

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
35° 32’ 43.2520” N, 119° 47’ 32.7755” W

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 injection well. The well will be worked over and recompleted as an EPA Class VI injection well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1941. The surface casing as shown in the **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing, long string casing, and liner details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 Directional

The well was drilled as a vertical well.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

Injection will be through tubing and a packer per 40 CFR 146.86(c)(2). Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative, Attachment K,** and **Table 10** and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected based on the proposed injection rate, composition, and reservoir conditions. The fluid flow model PROSPER[1] was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has Pressure-Volume-Temperature (PVT) correlations that have been validated for CO_2 injection with a wide range of impurities.

The tubing wall thickness was selected to account for corrosion wall loss including upset conditions for the selected grade. Corrosion wall loss estimates were determined using OLI,[2] an industry-standard commercial thermodynamic corrosion analysis program for aqueous systems.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	7,650	7,716
64 Zone Sandstone	7,785	7,985

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The operating injection pressure will depend on the reservoir pressure, the properties of the injected fluid, the wellbore friction, and the rate.

The annulus pressure will be maintained at a pressure higher than the tubing injection pressure as required per CFR 146.88(c). The maximum proposed pressure loads on the injection tubing and tubing by casing annulus are as follows:

- Maximum tubing injection pressure 2,800 pounds per square inch (psi)
- Maximum annulus pressure 2,900 psi
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

The maximum tubing injection and shut-in pressures are based on PROSPER flow assurance modeling. The maximum annulus pressure is higher than the maximum injection pressure as required per CFR 146.88(c).

After each casing and liner is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal or greater than the design pressure for that component to demonstrate mechanical integrity.

2.7 Injection Well Casing and Tubing Design

The new long string inner casing and tubing have been designed to withstand all expected loads during the life of the well including the maximum injection and annulus pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and

[1] https://www.petex.com
[2] https://olisystems.com

Attachment K were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the inner casing, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40
Axial – Compression (4)	1.40	1.40
1. VME Criterion (YS derated for temperature) 2. API Minimum Internal Yield Pressure 3. API (Tension adjusted) Collapse 4. API Pipe Body Yield Strength API: American Petroleum Institute VME: Von Mises Equivalent YS: Yield Strength		

2.7.1 Design Results without Corrosion

The new long string inner casing and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the design loads and the design results for the inner casing, inner liner and tubing are included in **Table 3**, **Table 4**, **Table 5,** and **Table 6** respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 7-inch Inner Casing Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.34	–	>3	–	2.50
3,950 psi Shut-in tubing pressure with methane to surface	1.72	–	>3	–	1.82

SF: safety factor

Table 4: 7-inch Inner Casing Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.34	–	>3	>3	2.50
3,950 psi Shut-in tubing pressure with methane to surface	1.72	–	>3	>3	1.82

Table 5: 4.5-inch Liner Nominal Wall Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure	2.22	–	>3	–	2.36
3,950 psi Shut-in tubing pressure with methane to surface	2.64	–	>3	–	2.82

Table 6: 4.5-inch Tubing Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure with 0 psi annulus pressure	2.69	–	>3	>3	2.73
3,950 psi Shut-in tubing pressure with methane to surface	1.97	–	2.40	–	1.98

2.7.2 Design Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing, inner liner, and tubing with respective remaining body wall (RBW) estimates are included in **Table 7**, **Table 8,** and **Table 9**, respectively. All safety factors exceed the design factors at the end of the injection phase.

The casing corrosion below the packer is not considered in the design because the 9-inch casing is isolated by the CRA inner casing through the caprock.

Table 7: 7-inch Inner Casing 77.7% RBW Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.08	–	>3	>3	1.93

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 injection well. The well will be worked over and recompleted as an EPA Class VI CO_2 injection well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1940. The surface casing as shown in the **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing and long-string casing details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 Directional

The well was drilled as a vertical well. The directional surveys are included in **Table 11**.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

Injection will be through tubing and a packer per 40 CFR 146.86(c)(2). Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative**, **Attachment K**, and **Table 10** respectively and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected based on the proposed injection rate, composition, and reservoir conditions. The fluid flow model PROSPER[1] was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has Pressure-Volume-Temperature (PVT) correlations that have been validated for CO_2 injection with a wide range of impurities.

The tubing wall thickness was selected to account for corrosion wall loss including upset conditions for the selected grade. Corrosion wall loss estimates were determined using OLI,[2] an industry-standard commercial thermodynamic corrosion analysis program for aqueous systems.

The maximum tubing injection and shut-in pressures are based on PROSPER flow assurance modeling. The maximum annulus pressure is higher than the maximum injection pressure as required by CFR 146.88(c).

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	7,650	7,757
64 Zone Sandstone	7,798	7,998

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The operating injection pressure will depend on the reservoir pressure, the properties of the injected fluid, the wellbore friction, and the rate.

The annulus pressure will be maintained at a pressure higher than the tubing injection pressure as required per CFR 146.88(c). The design pressure loads on the injection tubing and tubing by casing annulus are as follows:

- Maximum tubing injection pressure 2,800 pounds per square inch (psi)
- Maximum annulus pressure 2,900 psi
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

The maximum tubing injection and shut-in pressures are based on PROSPER flow assurance modeling. The maximum annulus pressure is higher than the maximum injection pressure as required per CFR 146.88(c).

After each casing and liner is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal or greater than the design pressure for that component to demonstrate mechanical integrity.

1. VME Criterion (YS derated for temperature) 2. API Minimum Internal Yield Pressure 3. API (Tension adjusted) Collapse 4. API Pipe Body Yield Strength API: American Petroleum Institute VME: Von Mises Equivalent YS: Yield Strength		

2.7.1 Design Results without Corrosion

The new long-string inner casing, liner, and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the dictating design loads and the design results for nominal wall thickness inner casing, liner, and tubing are included in **Table 3**, **Table 4**, **Table 5**, and **Table 6** respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: 9-1N Injection Well
API No.: 0402935107

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
35° 31’ 31.6480” N, 119° 46’ 37.0154” W

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 injection well. The well will be worked over and recompleted as an EPA Class VI injection well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1940–1941. The surface casing as shown in **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing, long-string casing, and liner details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 Directional

The well was drilled as a vertical well. The directional surveys are included in **Table 11**.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

Injection will be through tubing and a packer per 40 CFR 146.86(c)(2). Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative, Attachment K,** and **Table 10** respectively and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected based on the proposed injection rate, composition, and reservoir conditions. The fluid flow model PROSPER[1] was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has Pressure-Volume-Temperature (PVT) correlations that have been validated for CO_2 injection with a wide range of impurities.

The tubing wall thickness was selected to account for corrosion wall loss including upset conditions for the selected grade. Corrosion wall loss estimates were determined using OLI,[2] an industry standard commercial thermodynamic corrosion analysis program for aqueous systems.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	7,860	7,932
64 Zone Sandstone	8,001	8,201

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The operating injection pressure will depend on the reservoir pressure, the properties of the injected fluid, the wellbore friction, and the rate.

The annulus pressure will be maintained at a pressure higher than the tubing injection pressure as required per CFR 146.88(c). The design pressure loads on the injection tubing and tubing by casing annulus are as follows:

- Maximum tubing injection pressure 2,800 pounds per square inch (psi)
- Maximum annulus pressure 2,900 psi
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

The maximum tubing injection and shut-in pressures are based on PROSPER flow assurance modeling. The maximum annulus pressure is higher than the maximum injection pressure as required per CFR 146.88(c).

After each casing and liner is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal or greater than the design pressure for that component to demonstrate mechanical integrity.

2.7 Injection Well Casing, Inner Liner, and Tubing Design

The new long string inner casing, inner liner, and tubing have been designed to withstand all expected loads during the life of the well including the maximum injection and annulus pressure loads. The materials selected for these items as shown in **Attachment K** were based on corrosion

[1] https://www.petex.com
[2] https://olisystems.com

analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the inner casing, inner liner, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40
Axial – Compression (4)	1.40	1.40
1. VME Criterion (YS derated for temperature) 2. API Minimum Internal Yield Pressure 3. API (Tension adjusted) Collapse 4. API Pipe Body Yield Strength API: American Petroleum Institute VME: Von Mises Equivalent YS: Yield Strength		

2.7.1 Design Results without Corrosion

The new long-string inner casing, inner liner, and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the design loads and the design results for the inner casing, inner liner, and tubing are included in **Table 3**, **Table 4**, **Table 5**, and **Table 6**, respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 7-inch Inner Casing Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.34	–	>3	–	2.50
3,950 psi Shut-in tubing pressure with methane to surface	1.72	–	>3	–	1.82

SF: safety factor

Table 4: 7-inch Inner Casing Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.34	–	>3	>3	2.50
3,950 psi Shut-in tubing pressure with methane to surface	1.72	–	>3	>3	1.82

Table 5: 3.5-inch Inner Liner Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure	>3	–	>3	–	>3
3,950 psi Shut-in tubing pressure with methane to surface	>3	–	–	>3	>3

Table 6: 4.5-inch Tubing Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure with 0 psi annulus pressure	2.69	–	>3	>3	2.73
3,950 psi Shut-in tubing pressure with methane to surface	1.97	–	2.40	–	1.98

2.7.2 Design Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing, inner liner, and tubing with respective remaining body wall (RBW) estimates are included in **Table 7**, **Table 8**, and **Table 9**, respectively. All safety factors exceed the design factors at the end of the injection phase.

The liner corrosion is not considered in the design decision because it is entirely within the injection zone and well below the cap rock. The use of CRA materials and CO_2-resistant cement above the liner top ensure the pressure integrity of the well and the security of the storage reservoir.

Table 7: 7-inch Inner Casing 77.7% RBW Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.08	–	>3	>3	1.93
3,950 psi Shut-in tubing pressure with methane to surface	1.53	–	>3	>3	1.40

Table 8: 3.5-inch Inner Liner 73.5% RBW Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure with 0 psi annulus pressure	>3	–	>3	–	>3
3,950 psi Shut-in tubing pressure with methane to surface	>3	–	–	>3	>3

Table 9: 4.5-inch Tubing 73.2% RBW Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure with 0 psi annulus pressure	2.25	–	>3	>3	2.16
3,950 psi Shut-in tubing pressure with methane to surface	1.64	–	2.40	–	1.58

Table 10: Packer Information

Item	Value
Packer Setting Depth	7,550 ft
Packer material	Alloy 718 or equivalent
Packer element material	EPDM or HNBR
Packer type	Permanent or retrievable with latched seal assembly
Maximum casing ID	6.276 in. (nominal ID for 7 in. 26 ppf casing)
Minimum casing ID	6.151 in. (drift diameter for 7 in. 26 ppf casing)
Packer / seal assembly ID	4.500 in.
Packer rating	Differential pressure ±7,500 psi, axial capacity ±200,000 lbf, based on the packer loads in **Figure 1.**

EPDM: ethylene propylene diene monomer rubber
HNBR: hydrogenated nitrile butadiene rubber
ID: inner diameter
in: inches
lbf: pound-force
ppf: pounds per foot

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: 64-27N Injection Well
API No.: 0402935068

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
35° 32’ 38.0979” N, 119° 47’ 54.6576” W

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 injection well. The well will be worked over and recompleted as an EPA Class VI CO_2 injection well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1940. The surface casing as shown in **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing and long-string casing details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 Directional

The well was drilled as a vertical well.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

Injection will be through tubing and a packer per 40 CFR 146.86(c)(2). Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative, Attachment K,** and **Table 10** respectively and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected based on the proposed injection rate, composition, and reservoir conditions. The fluid flow model PROSPER[1] was used to determine the pressure and temperature profiles for CO_2 injection. PROSPER has Pressure-Volume-Temperature (PVT) correlations that have been validated for CO_2 injection with a wide range of impurities.

The tubing wall thickness was selected to account for corrosion wall loss including upset conditions for the selected grade. Corrosion wall loss estimates were determined using OLI,[2] an industry standard commercial thermodynamic corrosion analysis program for aqueous systems.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	7,558	7,647
64 Zone Sandstone	7,706	7,906

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The operating injection pressure will depend on the reservoir pressure, the properties of the injected fluid, the wellbore friction, and the rate.

The annulus pressure will be maintained at a pressure higher than the tubing injection pressure as required per CFR 146.88(c). The design pressure loads on the injection tubing and tubing by casing annulus are as follows:

- Maximum tubing injection pressure 2,800 pounds per square inch (psi)
- Maximum annulus pressure 2,900 psi
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

The maximum tubing injection and shut-in pressures are based on PROSPER flow assurance modeling. The maximum annulus pressure is higher than the maximum injection pressure as required per CFR 146.88(c).

After each casing and liner is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal to or greater than the design pressure for that component to demonstrate mechanical integrity.

2.7 Injection Well Casing, Liner, and Tubing Design

The new long-string inner casing, liner, and tubing have been designed to withstand all expected loads during the life of the well including the maximum injection and annulus pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and

[1] https://www.petex.com
[2] https://olisystems.com

Attachment K were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the inner casing, liner, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10

2.7.1 Design Results without Corrosion

The new long string inner casing, liner, and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the dictating design loads and the design results for nominal wall thickness inner casing, liner, and tubing are included in **Table 3**, **Table 4**, **Table 5**, and **Table 6** respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 6.625-inch Inner Casing Nominal Wall Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.40	–	>3	–	2.57
3,950 psi Shut-in tubing pressure with methane to surface	1.77	–	>3	–	1.87

SF: safety factor

Table 4: 6.625-inch Inner Casing Nominal Wall Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,900 psi Annulus operating pressure	2.40	–	>3	>3	2.57

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure	2.75	–	>3	–	3.00
3,950 psi Shut-in tubing pressure with methane to surface	2.68	–	>3	–	2.87

Table 6: 4.5-inch Tubing Nominal Wall Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
2,800 psi Injection pressure with 0 psi annulus pressure	2.69	–	>3	>3	2.73
3,950 psi Shut-in tubing pressure with methane to surface	1.97	–	2.40	>3	1.98

2.7.2 Design Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing, inner liner, and tubing are included in **Table 7**, **Table 8**, and **Table 9**, respectively. All safety factors exceed the design factors at the end of the injection phase.

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 monitoring well. The well will be worked over and recompleted as an EPA Class VI monitoring well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1937. The surface casing as shown in **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing and long-string casing details are included in **Section 5** of the **Application Narrative** and **Attachment K**. The 4.5-inch liner was run and cemented in 1940.

2.2 Directional

The well was drilled as a vertical well. The directional surveys are included in **Table 11**.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

The well will be completed with tubing and a packer. Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative**, and **Attachment K**, and **Table 10** respectively and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth

will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected to allow wireline tools to be run through the tubing for monitoring reservoir conditions as required per CFR 146.90.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
Agua	7,525	7,770
64 Zone Sandstone	8,029	8,069
64 Zone Sandstone	8,158	8,358

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The surface pressure for monitoring wells will depend on the reservoir pressure and the fluid gradient in the tubing.

The maximum pressure loads on the monitoring well tubing and tubing by casing annulus are as follows:

- Maximum shut-in tubing pressure with CO_2 1,850 pounds per square inch (psi)
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

After each casing is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal to or greater than the design pressure for that component to demonstrate mechanical integrity.

2.7 Monitoring Well Casing and Tubing Design

The new long-string inner casing and tubing have been designed to withstand all expected loads during the life of the well, including the maximum surface pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and **Attachment K** respectively and were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the inner casing, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10

2.7.1 Design Results without Corrosion

The new long-string inner casing and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the design loads and the design results for the inner casing and tubing are included in **Table 3**, **Table 4**, **Table 5**, and **Table 6**, respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 7-inch Inner Casing Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	>3	–	>3	>3	>3
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.86	–	>3	–	1.98

SF: safety factor

Table 4: 7-inch Inner Casing Design Results Section 2

Late life SI with CO_2 to Surface	>3	–	>3	>3	>3
Late life SI with CH_4 to Surface	>3	–	2.93	>3	2.70

SI: shut-in

2.7.2 Design Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing and tubing with respective remaining body wall (RBW) estimates are included in **Table 7**, **Table 8**, and **Table 9** respectively. All safety factors exceed the design factors at the end of the injection phase except load "3,950 psi Shut-in Injection Tubing Leak (CH_4)" as shown in **Table 7**.

The end-of-life triaxial safety factor is slightly less than the design factor of 1.25 for the conservative and unlikely load of methane to surface. If the surface pressure approaches the design load pressure, the well can be killed to maintain safe operations. Based on this unlikely load occurring and available mitigation, the design is considered acceptable.

Table 7: 7-inch Inner Casing 61.9% RBW Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	2.53	–	–	>3	2.24
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.31	–	>3	>3	1.20

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: 25-26N (Monitoring Agua)
API No.: 0402935053

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
35°33'1.2506"N, 119°47'43.8785"W

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 monitoring well. The well will be worked over and recompleted as an EPA Class VI monitoring well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1938–1939. The original 4.75-inch liner was plugged in 1939 due to high water cut. A whipstock was set in the 9-inch casing at 6,244 feet (ft) and sidetracked. A 6.625-inch casing was set at 8,133 ft. The sidetrack was completed in the lower 64 zone with a 4.75-inch slotted liner.

The surface casing as shown in the **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing and long string casing details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 Directional

The well was drilled as a vertical well. A sidetrack was drilled 400 ft to the southwest to 8,300 ft through 9-inch casing at 6,244 ft. The directional surveys are included in **Table 9**.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

The well will be completed with tubing and a packer. Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative**, **Attachment K**, and **Table 8** respectively and were selected to ensure compatibility with the injected and reservoir fluids as required by 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected to allow wireline tools to be run through the tubing for monitoring reservoir conditions as required per CFR 146.90.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
Agua	7,687	7,749

2.6 Maximum Surface Pressures and Mechanical Integrity

The surface pressure for monitoring wells will depend on the reservoir pressure and the fluid gradient in the tubing. The maximum pressure loads on the monitoring well tubing and tubing by casing annulus are as follows:

- Maximum shut-in tubing pressure with CO_2 1,850 pounds per square inch (psi)
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

After each casing is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal or greater than the design pressure for that component to demonstrate mechanical integrity.

2.7 Monitoring Well Casing and Tubing Design

The new long string inner casing and tubing have been designed to withstand all expected loads during the life of the well including the maximum surface pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and **Attachment K** were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the inner casing, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40
Axial – Compression (4)	1.40	1.40
1. VME Criterion (YS derated for temperature) 2. API Minimum Internal Yield Pressure 3. API (Tension adjusted) Collapse 4. API Pipe Body Yield Strength API: American Petroleum Institute VME: Von Mises Equivalent YS: Yield Strength		

2.7.1 Design Results without Corrosion

The new long string inner casing and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the design loads and the design results for the inner casing and tubing are included in **Table 3**, **Table 4**, and **Table 5**. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 4.5-inch Inner Casing Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	>3	–	>3	>3	>3
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.99	–	>3	–	2.09

SF: safety factor

Table 4: 4.5-inch Inner Casing Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	>3	–	–	>3	>3
3,950 psi Shut-in Injection Tubing Leak (CH_4)	2.36	>3	>3	–	2.46

Table 5: 2.375-inch Tubing Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	>3	–	>3	>3	>3
Late life SI with CH_4 to Surface	>3	–	2.93	>3	2.70

SI: shut-in

2.7.2 Design Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing, inner liner, and tubing with respective remaining body wall (RBW) estimates are included in **Table 6** and **Table 7**. All safety factors exceed the design factors at the end of the injection phase except load "3950 psi Shut-in Injection Tubing Leak (CH_4)."

The triaxial safety factor is 1.22, which is slightly less than the design factor of 1.25. This conservative load is a design load than can be monitored. If the surface pressure approaches the design pressure, the well will be killed, and corrective action will take place to make the well safe. Based on this unlikely load occurring and available mitigation, the design is considered acceptable.

Table 6: 4.5-inch Inner Casing 50.5% RBW Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	2.63	–	–	>3	2.32
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.36	–	>3	–	1.22

Table 7: 2.375-inch Tubing 38.8% RBW Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	2.67	–	>3	>3	2.49
Late life SI with CH_4 to Surface	1.36	–	2.93	3	1.33

Table 8: Packer Information

Item	Value
Packer Setting Depth	7,600 ft
Packer material	Alloy 718 or equivalent
Packer element material	EPDM or HNBR
Packer type	Permanent or retrievable with latched seal assembly
Maximum casing ID	3.958 in. (nominal ID for 4.5 in. 12.6 ppf casing)

Item	Value
Minimum casing ID	3.833 in. (drift diameter for 4.5 in. 12.6 ppf casing)
Packer / seal assembly ID	1.995 in. (based on tubing drift ID)
Packer rating	Differential pressure ±7,500 psi, axial capacity ±40,000 lbf, based on the packer loads in **Figure 1** .

EPDM: ethylene propylene diene monomer rubber
HNBR: hydrogenated nitrile butadiene rubber
ID: inner diameter
in: inches
lbf: pound force
ppf: pounds per foot

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: 27-1N (Monitoring 64 Sands)
API No.: 0402935115

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
35°31'18.6498"N, 119°46'21.0202"W

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a carbon dioxide (CO_2) monitoring well. The well will be worked over and recompleted as an EPA Class VI monitoring well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1939. The surface casing, as shown in **Section 5** of the **Application Narrative** and **Attachment K,** was set and cemented to surface. The intermediate casing and long-string casing details are included in **Section 5** of the **Application Narrative** and **Attachment K**. The 5.5-inch liner was run and cemented in 1985.

2.2 Directional

The well was drilled as a vertical well. The directional surveys are included in **Table 11**.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

The well will be completed with tubing and a packer. Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative**, **Attachment K**, and **Table 10** respectively and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR

146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected to allow wireline tools to be run through the tubing for monitoring reservoir conditions as required per CFR 146.90.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	8,001	8,070
64 Zone Sandstone	8,102	8,302

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The surface pressure for monitoring wells will depend on the reservoir pressure and the fluid gradient in the tubing.

The maximum pressure loads on the monitoring well tubing and tubing by casing annulus are as follows:

- Maximum shut-in tubing pressure with CO_2 1,850 pounds per square inch (psi)
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

After each casing is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal to or greater than the design pressure for that component to demonstrate mechanical integrity.

2.7 Monitoring Well Casing and Tubing Design

The new long-string inner casing and tubing have been designed to withstand all expected loads during the life of the well including the maximum surface pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and **Attachment K** were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the inner casing, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40
Axial – Compression (4)	1.40	1.40

1. VME Criterion (YS derated for temperature)
2. API Minimum Internal Yield Pressure
3. API (Tension adjusted) Collapse
4. API Pipe Body Yield Strength

API: American Petroleum Institute
VME: Von Mises Equivalent
YS: Yield Strength

2.7.1 Design Results without Corrosion

The new long-string inner casing, and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the design loads and the design results for the inner casing and tubing are included in **Table 3**, **Table 4**, **Table 5**, and **Table 6**, respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 5.5-inch Inner Casing Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	>3	–	>3	–	>3
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.79	–	>3	–	1.90

SF: safety factor

Table 4: 5.5-inch Inner Casing Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	>3	–	–	>3	>3
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.98	–	>3	–	2.07

Table 5: 3.5-inch Inner Casing Design Results Section 3

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	>3	–	>3	–	>3
Late life SI with CH_4 to Surface	2.58	–	>3	–	2.66

SI: shut-in

Table 6: 2.375-inch Tubing Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	>3	–	>3	>3	>3
Late life SI with CH_4 to Surface	>3	–	2.93	>3	2.70

2.7.2 Design Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing and tubing with respective remaining body wall (RBW) estimates are included in **Table 7, Table 8**, and **Table 9**, respectively. All safety factors exceed the design factors at the end of the injection phase except the triaxial safety factor for load "3,950 psi Shut-in Injection Tubing Leak (CH_4)," as shown in **Table 7**.

The end-of-life triaxial safety factor for 5.5-inch inner casing is slightly less than the design factor of 1.25 for the conservative and unlikely load of methane to surface. If the surface pressure approaches the design load pressure, the well can be killed to maintain safe operations. Based on this unlikely load occurring and available mitigation, the design is considered acceptable.

Table 7: 5.5-inch Inner Casing 57.1% RBW Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	2.49	–	–	>3	2.22
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.29	–	>3	–	1.17

Table 8: 3.5-inch Inner Casing 51.1% RBW Design Results Section 3

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	2.92	–	–	>3	2.56
Late life SI with CH_4 to Surface	1.51	–	>3	>3	1.35

Table 9: 2.375-inch Tubing 38.8% RBW Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	2.67	–	>3	>3	2.49
Late life SI with CH_4 to Surface	1.36	–	2.93	>3	1.33

Table 10: Packer Information

Item	Value
Packer Setting Depth	7,800 feet
Packer material	Alloy 718 or equivalent
Packer element material	EPDM or HNBR
Packer type	Permanent or retrievable with latched seal assembly
Maximum casing ID	6.276 in. (nominal ID for 7 in. 26 ppf casing)
Minimum casing ID	6.151 in. (drift diameter for 7 in. 26 ppf casing)
Packer / seal assembly ID	1.995 in. (based on tubing drift ID)
Packer rating	Differential pressure ±7,500 psi, axial capacity ±40,000 lbf, based on the packer loads in **Figure 1** .

EPDM: ethylene propylene diene monomer rubber
HNBR: hydrogenated nitrile butadiene rubber
ID: inner diameter
in.: inches
lbf: pound force
ppf: pounds per foot

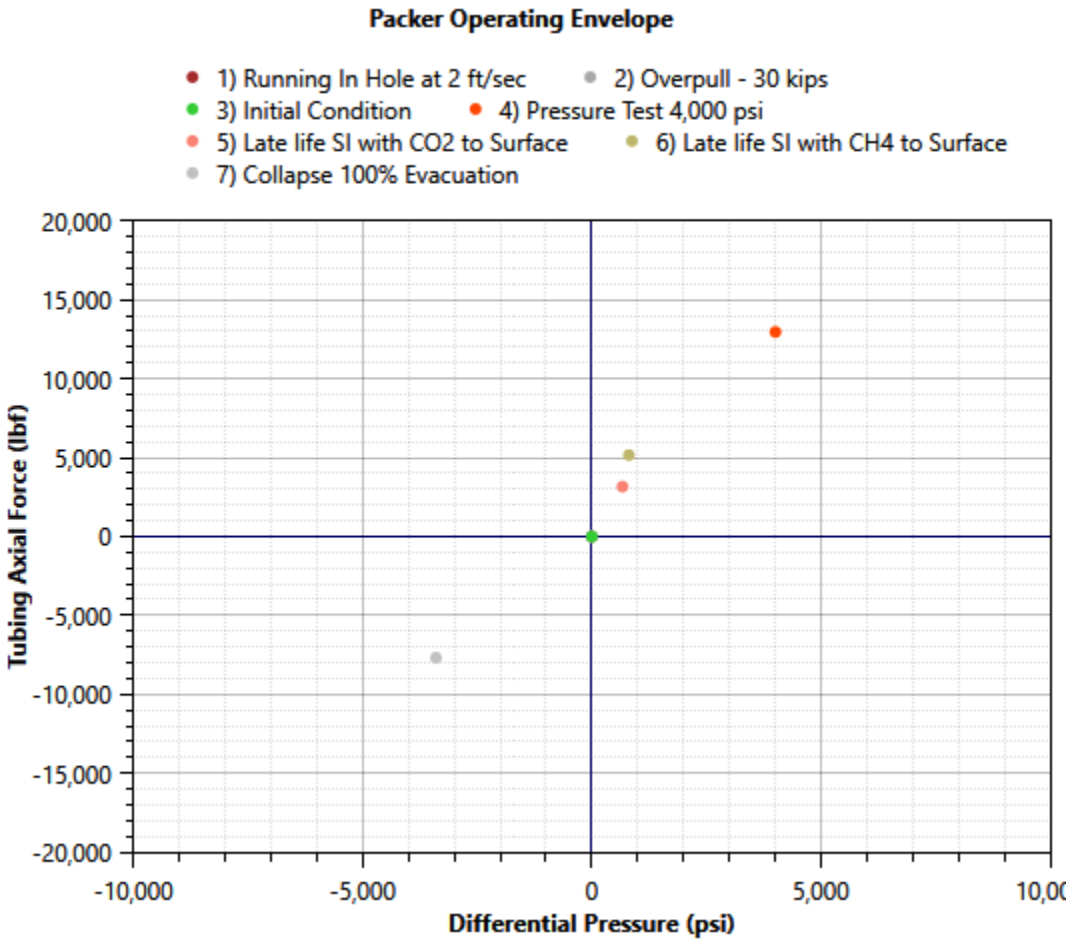

Figure 1: Packer Loads

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name: CarbonFrontier
Well name: 35X-27N (Monitoring Lower Carneros)
API No.: 0402958271

Facility contact: Randy Hoyle, Chief Carbon Solutions Officer
10000 Ming Ave., Bakersfield, CA 93311
(661) 665-5000, RWHoyle@aeraenergy.com

Well location: Kern County, CA
35°32'59.2890"N, 119°48'2.9031"W

1. INTRODUCTION

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a CO_2 monitoring well. The well will be worked over and recompleted as a CO_2 above-zone monitoring well.

2. WELL DESIGN

2.1 Well History

The original well was drilled in 1978. The surface casing as shown in **Section 5** of the **Application Narrative** and **Attachment K** was set and cemented to surface. The intermediate casing and long-string casing details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 Directional

The well was drilled as a vertical well. The directional surveys are included in **Table 6**.

2.3 Underground Sources of Drinking Water

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 Tubing and Packer

The well will be completed with tubing and a packer. Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative**, **Attachment K**, and **Table 5**. This is an above-zone observation well completed in the Lower Carneros Sandstones. The tubing and packer will not be exposed to CO_2. The packer will be set in the casing opposite a cemented interval.

The tubing size was selected to allow wireline tools to be run through the tubing for monitoring reservoir conditions as required per CFR 146.90.

2.5 Proposed Perforations

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
Lower Carneros	6,566	6,690
Lower Carneros	6,755	6,938

ft: feet

2.6 Maximum Surface Pressures and Mechanical Integrity

The maximum pressure loads on the monitoring well tubing and casing are as follows:

- Maximum casing pressure test 1,000 pounds per square inch (psi)
- Maximum shut-in tubing pressure with CO_2 1,850 psi
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

2.7 Monitoring Well Casing and Tubing Design

The new tubing and casing have been designed to withstand all expected loads during the life of the well including the maximum surface pressure loads.

The loads were evaluated and compared to the strengths to determine an appropriate well design including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40
Axial – Compression (4)	1.40	1.40

1. VME Criterion (YS derated for temperature)
2. API Minimum Internal Yield Pressure
3. API (Tension adjusted) Collapse
4. API Pipe Body Yield Strength

API: American Petroleum Institute
VME: Von Mises Equivalent
YS: Yield Strength

2.7.1 Design Results

The casing and tubing details are shown in **Section 5** of the **Application Narrative** and **Attachment K**.

A description of the design loads and the design results for the casing and tubing are included in **Table 3** and **Table 4**. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 7-inch Casing Design Results

Casing Section	Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1	Pressure test 1,000 psi	>3	–	>3	–	>3
2	Pressure test 1,000 psi	>3	–	>3	–	>3
3	Pressure test 1,000 psi	1.45	>3	>3	>3	1.54
4	Pressure test 1,000 psi	2.38	–	>3	>3	2.46

SF: safety factor

Table 4: 2.375-inch Tubing Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	>3	–	>3	>3	>3
Late life SI with CH4 to Surface	>3	–	>3	–	2.90

SI: shut-in

Table 5: Packer Information

Item	Value
Packer Setting Depth	6,450 ft
Packer material	Carbon steel
Packer element material	EPDM or HNBR
Packer type	Permanent or retrievable with latched seal assembly
Maximum casing ID	6.366 in. (nominal ID for 7 in. 23 ppf casing)
Minimum casing ID	6.241 in. (drift diameter for 7 in. 23 ppf casing)
Packer / seal assembly ID	1.995 in. (based on tubing drift ID)
Packer rating	Differential pressure ±7,500 psi, axial capacity ±150,000 lbf, based on the packer loads in **Figure 1 .**

EPDM: ethylene propylene diene monomer rubber
HNBR: hydrogenated nitrile butadiene rubber
ID: inner diameter
in.: inches
lbf: pound force
ppf: pounds per foot

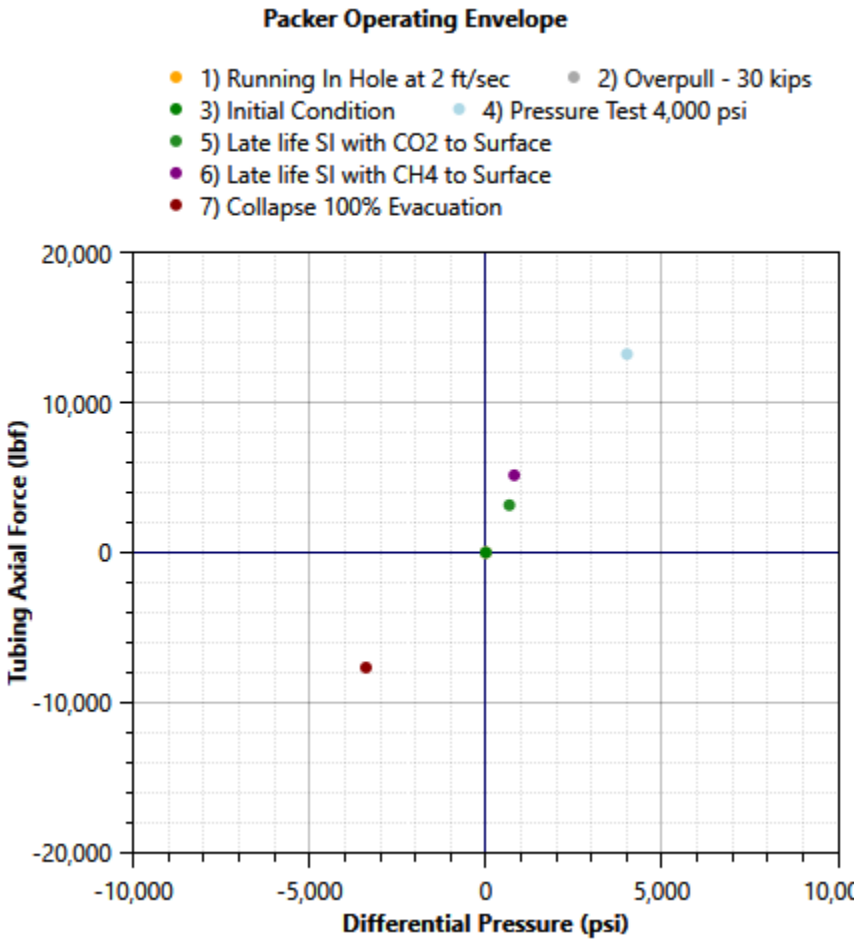

Figure 1: Packer Loads

CONSTRUCTION DETAILS

AERA ENERGY, LLC - CARBONFRONTIER

FACILITY INFORMATION

Facility name:	CarbonFrontier
Well name:	39-26N (Monitoring 64 Sands)
API No.:	0402935054
Facility contact:	Randy Hoyle, Chief Carbon Solutions Officer 10000 Ming Ave., Bakersfield, CA 93311 (661) 665-5000, RWHoyle@aeraenergy.com
Well location:	Kern County, CA 35°32'54.8149"N, 119°47'35.1082"W

1. Introduction

The well construction details provided in this document are well-specific and supplement details presented in Construction Details (**Attachment K**) and **Section 5** of the **Application Narrative**. The well is an existing well that will be repurposed and converted to a carbon dioxide (CO_2) monitoring well. The well will be worked over and recompleted as an EPA Class VI monitoring well.

2. Well Design

2.1 *Well History*

The original well was drilled in 1938. In 1939, the 9-inch casing was cut at 5,975 feet (ft) and pulled. A whipstock was set in the 11.75-inch casing at 5,765 ft, and the well was sidetracked. The 7-inch casing was run and cemented at 8,100 feet, and a 4.75-inch slotted liner was set at 8,232 ft.

The surface casing, as shown in **Section 5** of the **Application Narrative** and **Attachment K**, was set and cemented to surface. The long-string casing details are included in **Section 5** of the **Application Narrative** and **Attachment K**.

2.2 *Directional*

The well was drilled as a vertical well. The directional surveys are included in **Table 9**.

2.3 *Underground Sources of Drinking Water*

The Tulare formation is the only potential underground source of drinking water but has an approved Aquifer Exemption.

2.4 *Tubing and Packer*

The well will be completed with tubing and a packer. Materials for the tubing and packer are shown in **Section 5** of the **Application Narrative, Attachment K,** and **Table 8** and were selected to ensure compatibility with the injected and reservoir fluids as required per 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented.

The tubing size was selected to allow wireline tools to be run through the tubing for monitoring reservoir conditions as required per CFR 146.90.

2.5 *Proposed Perforations*

Table 1 shows the proposed perforations intervals for the well.

Table 1: Proposed Perforations

Zone	Perforations Top (ft)	Perforations Bottom (ft)
64 Zone Sandstone	7,975	8,038
64 Zone Sandstone	8,105	8,243

2.6 *Maximum Surface Pressures and Mechanical Integrity*

The surface pressure for monitoring wells will depend on the reservoir pressure and the fluid gradient in the tubing.

The maximum pressure loads on the monitoring well tubing and tubing by casing annulus are as follows:

- Maximum shut-in tubing pressure with CO_2 1,850 pounds per square inch (psi)
- Maximum shut-in tubing pressure with methane (CH_4) 3,950 psi

After the casing is set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal to or greater than the design pressure for that component to demonstrate mechanical integrity.

2.7 *Monitoring Well Casing and Tubing Design*

The new long-string inner casing and tubing have been designed to withstand all expected loads during the life of the well, including the maximum surface pressure loads. The materials selected for these items as shown in **Section 5** of the **Application Narrative** and **Attachment K** were based on corrosion analysis to ensure that the materials are compatible with the injected and reservoir fluids. The upper casing section will be carbon steel with a corrosion-resistant alloy (CRA) lower section for compatibility with the injected and reservoir fluids per CFR 146.86(b)(1). The flow-wetted lower part of the inner casing, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to determine an appropriate well design, including safety factors. **Table 2** shows the design factors (minimum safety factors) used in the analysis.

Table 2: Design Factors

Failure Mode	Casing	Tubing
Triaxial (1)	1.25	1.25
Burst (2)	1.30	1.20
Collapse (3)	1.00	1.10
Axial – Tension (4)	1.60	1.40
Axial – Compression (4)	1.40	1.40
1. VME Criterion (YS derated for temperature) 2. API Minimum Internal Yield Pressure 3. API (Tension adjusted) Collapse 4. API Pipe Body Yield Strength API: American Petroleum Institute VME: Von Mises Equivalent YS: Yield Strength		

2.7.1 Design Results without Corrosion

A description of the design loads and the design results for the inner casing and tubing are included in **Table 3**, **Table 4**, and **Table 5,** respectively. All safety factors exceed the design factors. Additional details on the tubular design are available in the FEED Study for the Aera North Belridge CCS Project design report.

Table 3: 4.5-inch Inner Casing Design Results Section 1

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	>3	–	>3	>3	>3
3,950 psi Shut-in Injection Tubing Leak (CH_4)	1.99	–	>3	–	2.11

SF: safety factor

Table 4: 4.5-inch Inner Casing Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1,850 psi Shut-in Injection Tubing Leak (CO_2)	>3	–	>3	>3	>3
3,950 psi Shut-in Injection Tubing Leak (CH_4)	2.36	–	>3	>3	2.48

Table 5: 2.375-inch Tubing Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	>3	–	>3	>3	>3
Late life SI with CH_4 to Surface	>3	–	2.92	>3	>3

SI: shut-in

2.7.2 Design Results with Corrosion

The wall thickness may reduce with time because of corrosion. Corrosion analysis using a corrosion model was used to estimate wall loss at the end of the injection period. The design results for the inner casing and tubing with remaining body wall (RBW) estimates are included in **Table 6** and **Table 7**, respectively. All safety factors exceed the design factors at the end of the injection phase except the triaxial safety factor for load "3950 psi Shut-in Injection Tubing Leak (CH_4)," as shown in **Table 6**.

The triaxial safety factor is slightly less than the design factor of 1.25. The conservative design load can be monitored. If this load approaches the design pressure, the well will be killed, and corrective action will take place to make the well safe. Based on this conservative load assumption and available mitigation, the design is considered acceptable.

Table 6: 4.5-inch Inner Casing 50.5% RBW Design Results Section 2

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
1850 psi Shut-in Injection Tubing Leak (CO_2)	1.75	–	>3	>3	1.55
3950 psi Shut-in Injection Tubing Leak (CH_4)	1.36	–	>3	–	1.23

Table 7: 2.375-inch Tubing 38.8% RBW Design Results

Load	Burst SF	Collapse SF	Tension SF	Compression SF	Triaxial SF
Late life SI with CO_2 to Surface	2.64	–	>3	>3	2.47
Late life SI with CH_4 to Surface	1.34	–	2.92	3	1.32

Table 8: Packer Information

Item	Value
Packer Setting Depth	7,850 ft
Packer material	Alloy 718 or equivalent
Packer element material	EPDM or NHBR
Packer type	Permanent or retrievable with latched seal assembly
Maximum casing ID	4.000 in. (nominal ID for 4.5 in. 11.6 ppf casing)
Minimum casing ID	3.875 in. (drift diameter for 4.5 in. 11.6 ppf casing)
Packer / seal assembly ID	1.995 in. (based on tubing drift ID)
Packer rating	Differential pressure ±7,500 psi, axial capacity ±40,000 lbf, based on the packer loads in **Figure 1** .

EPDM: ethylene propylene diene monomer rubber
HNBR: hydrogenated nitrile butadiene rubber
ID: inner diameter
in.: inches
lbf: pound force
ppf: pounds per foot

FEED Study for the Aera North Belridge CCS Project

Final Report

FEED Study for the Aera North Belridge CCS Project

Prepared for:
Aera Energy

Purpose:
Document the injection well design study results, recommendations, and analyses for the North Belridge CCS project.

Date: December 20, 2023

Version: 3

Project Number: AER-22-011

Blade Energy Partners, Ltd. and its affiliates (Blade) provide our services subject to our General Terms and Conditions (GTC) in effect at time of service, unless a GTC provision is expressly superseded in a separate agreement made with Blade. Blade's work product is based on information sources which we believe to be reliable, including information that was publicly available and that was provided by our client; but Blade does not guarantee the accuracy or completeness of the information provided. All statements are the opinions of Blade based on generally-accepted and reasonable practices in the industry. Our clients remain fully responsible for all clients' decisions, actions and omissions, whether based upon Blade's work product or not; and Blade's liability solely extends to the cost of its work product. This report is sensitive and confidential and contains confidential information that is intended only for the one or more individual(s) or entity(ies) for whom Blade prepared this report.

Version Record

Version	Issue Date	Issued As/ Type of Version	Authors	Checked By	Project Leader
1	Sep. 21, 2022	Final Report	RLR, PVS, GA, NC	PVS	PVS
2	Nov. 11, 2022	Final Report	RLR, RMK	RLR	PVS
3	Dec. 20, 2023	Final Report	RLR, GA	RLR	PVS

Version History

Version	Date	Description of Change
2	Nov. 11, 2022	Updated to reflect changes in the well proposed for repurposing. Removed the Option 2 well designs (long string casing set through the injection zone). Added load analysis for 9 in. casing. Added Well Construction Components materials recommendations.
3	Dec. 20, 2023	Updated the final reservoir pressure to 4,350 psi at 7,007 ft and the injection temperature to 180°F and re-ran PROSPER analysis. Removed the big bore new drill option. Updated the wellbore schematics. Re-ran and updated the well design results. The updated results were used to update the EPA well construction permitting documents.

Table of Contents

1 **Executive Summary** **9**

2 **Conclusions and Results** **12**

2.1 Well Performance Analysis 12

2.2 Material Selection 12

2.3 Well Design Overview 13

3 **Introduction** **20**

4 **Well Performance** **22**

4.1 Defining PROSPER Well Models for CO_2 22

4.2 64-Zone Well Match and Injectivity Model 26

4.3 Well 64-35N Match and CO_2 Injectivity Study 27

4.4 Well 64-27N Match and CO_2 Injectivity Study 39

4.5 Well 49-35N Match and CO_2 Injectivity Study 42

4.6 64-Zone Injection Test Design 44

4.7 64-Zone Injection Sensitivity for Reservoir Modeling 50

4.8 Temperature and Pressure Update for 64-25N 51

5 **Materials Selection** **54**

5.1 Background 54

5.2 H_2O Solubility in Super Critical CO_2 55

5.3 Corrosion Evaluation 57

5.4 Well Construction Components 71

5.5 Discussion 72

5.6 Conclusions 73

6 **Injection Wells Design and Analysis** **75**

6.1 Design Approach 75

6.2 Design Load Cases 78

6.3 Remaining Wall Thickness Results Summary 84

6.4 PROSPER Analysis for Well Design Loads 87

6.5 Well 9-1N Repurposed Well Design 89

6.6 Well 64-35N Repurposed Well Design 114

6.7 Well 64-27N Repurposed Well Design 117

6.8 Well 27R-27N Repurposed Well Design 125

6.9 Well 55-26N Repurposed Well Design 128

6.10 New Drill Injection Well Design 130
6.11 API RP 90-2 MAWOP Analysis 143
6.12 Cementing Comments and Recommendations 144
6.13 Casing and Tubing Connections 146
6.14 Annular Pressure Management 146
7 Nomenclature 148
7.1 Abbreviations and Acronyms 148
8 References 150
9 Appendix A—Materials Additional Information 152
9.1 Alloy Composition 152
9.2 Temperature and Pressure Profile Inputs to Thermodynamic Models 152
9.3 Effect of NH_3 in pH and Corrosion of Carbon Steel and 13Cr 153
10 Appendix B—Reliability Based Design Overview 155
11 Appendix C—Undisturbed Temperature Profile 157
12 Appendix D—Pore Pressure and Fracture Pressure 158
13 Appendix E—Cementing Design Assumptions 161
14 Appendix F—Design Analysis Results for 9 in. Casing 162
14.1 9 in. Casing with Nominal Wall Design Results 162

1 Executive Summary

Aera Energy (Aera) is pursuing a project to sequester CO_2 in the depleted 64 Zone oil sands of their North Belridge field. The field is located northwest of Bakersfield, California in Kern County. Initially, CO_2 emissions from produced gas will be injected. Longer term plans include injection of post-combustion CO_2. In addition to repurposing existing wells as injectors or monitoring wells, Aera are also considering new drill wells for injection.

Blade Energy Partners (Blade) was contracted to provide a comprehensive Front-End Engineering and Design (FEED) study in support of Aera's planned Class VI well permit application for a Carbon Capture and Sequestration (CCS) project. Blade was also commissioned to write the permit documents for the well construction package to be submitted to EPA. This report covers the FEED study.

The integrated, multi-disciplinary study was conducted using Blade's rigorous Front-End Engineering and Design (FEED) process, and focused on the following interconnected areas of work:

- Well performance analysis and flow assurance,
- Corrosion analysis and Materials selection, and
- Injection well design and analysis, for both repurposed and new-drill wells

Aera has provided extensive well and field data, and other source material. These were used to prepare the design premise document (DPD). Version 5 of the DPD, *Aera CO2 North Belridge Injection Wells Design DPD* [1] was approved by Aera and formed the basis for this study. The DPD includes the data and assumptions, and casing, tubing, and liner design loads that were used in the analysis. All aspects of the study used these assumptions to maintain consistency across disciplines.

The North Belridge Field consists of many existing wells, and most of the wells were drilled in the 1930s and 1940s timeframe. Aera wishes to repurpose existing wells for CO_2 injection and observation (monitoring) wells. Some of the wells were completed with non-API 9 in. OD production casing. For repurposing, candidate wells that have usable wellbores and are located where it is desirable to inject and monitor the injection of CO_2 were selected from the existing well database. The repurposed wells will have inner casing and liners cemented inside existing wellbores to result in a well that meets EPA Class VI requirements. Some of the existing wells have cemented liners and some have un-cemented liners. Wells with cemented liners well be repurposed by cementing corrosion resistant alloy (CRA) inner liners to isolate the carbon steel liners. Un-cemented liners will be pulled and replaced with cemented liners. In addition to evaluating well designs for repurposed wells, well designs for new drill wells are included in case there is a need to add new injection wells. A list of the proposed repurposed wells is shown in Table 2.

The first step in Blade's study was well performance and flow assurance analysis. PROSPER[i], a commercial production engineering program, was used to model the injection of CO_2 with impurities. Analysis was performed for the repurposed wells and for the new drills. The target injection rate for wells with 4 1/2 in. tubing is 20 MMscf/day. The estimated injection pressure at surface is assumed to be 2,400 psig, with an injection temperature of 94°F for a final reservoir pressure of 4,200 psi. In all cases, the estimated starting reservoir pressure is assumed to be 700 psig. Based on the analysis, the optimal choice for tubing size for the repurposed wells is 4 1/2 inch OD. For the new drill wells, the recommended tubing size is also 4 1/2 inch OD based on discussions with Aera. It is shown that injection

[i] https://www.petex.com/products/ipm-suite/prosper/. PROSPER has PVT models that have been validated for CO_2 injection with a wide range of impurities.

stream temperature has a substantial impact on the stability of injection flow, and inlet temperature management will be required to provide flow assurance.

The well performance evaluation also included an analysis of historical injectivity tests for five wells to estimate the permeability thickness of the reservoir rock and injectivity. Results from this analysis were used to define the assumptions and sensitivity ranges for flow performance and assurance analysis. Well injection sensitivity charts are presented to assist in reservoir modeling. The wells investigated showed that 10 to 30 MMscf/D could be injected per well in a repurposed well. However, it should be noted that the presence of water can significantly reduce the relative permeability of CO_2, and thus adversely affect injection rates. Field injection tests are recommended to determine a well's injection area permeability to CO_2, skin, and average pressure. An injection test design is included as part of the study.

Corrosion is one of the key factors considered in selecting the tubing (and liner/casing) material appropriate for carbon capture and storage (CCS) well applications. The commercial thermodynamic modeling software OLI[ii] was utilized to quantify the corrosion rates for carbon steel, and corrosion resistant materials. This was supplemented by research into current literature, especially experimental work on corrosion in CO_2 rich flow streams. First, water solubility in supercritical (dense phase) CO_2 with and without impurities was established and contextualized to existing literature. Impurities decrease the solubility of water in dense phase CO_2, leading to precipitation of water and creation of a corrosive, low pH fluid. Next, corrosion analysis was performed, using OLI and results from the well performance analysis, for a wide range of materials in wet CO_2, with and without impurities. With dry injectate (containing less than 500 ppm H_2O), the corrosion rate is negligible. However, it is important to consider the presence of water during upset conditions. Finally, corrosion due to exposure to reservoir fluid with wet CO_2 was investigated for a range of mixing conditions. Based on this analysis, it was concluded that modified 13Cr is suitable for CCS injection wells. The casing and tubing design analysis in this report is based on modified 13Cr80 and 13Cr110 material depending on the load requirements. Recommendations are included for other flow wetted components including the wellhead, packer, and downhole completion equipment.

Well design (tubulars and connections) was performed using StrinGnosis[iii], a commercial wellbore thermal analysis and tubular design software program. StrinGnosis has the capability to evaluate anisotropic materials and conduct reliability-based design (RBD), both of which are important for CCS well engineering. An overview of RBD is included in Section 10. RBD was used to determine the probability of exceedance and failure if the safety factor was less than the design factor. EPA Class VI injection wells require holding annulus pressure higher than the tubing injection pressure. API RP 90-2 provides recommended derating factors for casing and tubing to calculate the maximum allowable wellhead operating pressure (MAWOP) for wells operated with annulus pressure. The injection casing and tubing designs were evaluated to determine the MAWOP that meet RP 90-2 requirements for various operating scenarios that considered wall thickness, grade, wall loss from corrosion, and annulus pressure.

Repurposed wells are being considered for use as CO_2 injection wells. The 9 in. and 8 1/8 in. production casing in existing wells was evaluated for injection well loads and found to be inadequate in burst strength to meet the design requirements. The wells being considered were drilled in the 1930s and 1940s using non-API casing. Based on the design load analysis and the age of the wells, the recommendation is to install new inner casing with cement to surface which results in a well design that

[ii] OLIsystems.com

[iii] StrinGnosis was developed and is marketed by Blade Technology Corporation, a wholly owned subsidiary of Blade Energy Partners.

meets EPA Class IV requirements. The results presented in this report are based on repurposing wells with an inner casing.

Multiple well types were evaluated in this document. The nomenclature used for the well types include:

- Well type: Repurposed wells with a cemented liner
- Well type: Repurposed wells with an un-cemented liner
- Well type: New drill well with 7 in. casing and a 4 1/2 in. liner

This document covers the well design analysis for a total of four injection well types. It is planned to use this document as the basis for writing the Well Construction permit documents. Well design analysis results for repurposed observation wells are presented in a separate report *Aera North Belridge CCS Observation Well Design Analysis* [1].

Key conclusions and recommendations of the FEED study are presented in the following section.

November 2023 update. The design reservoir pressure was updated to 4,340 psi and the injection temperature at the wellhead was changed to 180°F. Flow assurance was evaluated based on the revised injection parameters to determine the pressure and temperature profiles to update the design loads. This FEED study report was updated with the well design results.

2 Conclusions and Results

The main conclusions and recommendations are summarized in this section. Additional details can be found in the body of the report.

2.1 Well Performance Analysis

The well performance analysis study on the Belridge 64-Zone includes the following:

- CO_2 injectivity for three wells with sufficient data to model injectivity
- CO_2 injection test design for measuring injectivity of wells
- CO_2 injectivity modeling in support of Aera's reservoir simulation modeling

A number of sensitivities are performed to determine the feasible injection rates. The effect of increasing reservoir pressure with time is investigated, and it is shown that inlet temperature management will be required to assure stable injection. The wells investigated show that 10 to 30 MMscf/D can be injected per well in a repurposed well. The optimum tubing size for a repurposed well is 4 1/2 in. because this reduces friction compared to smaller tubing sizes that would otherwise require an increase in compression. Some locations have injectivity that could support greater rates for new wells drilled with bigger wellbores. The ability to sustain rates is an issue Aera is investigating through reservoir simulation.

The reservoir pressure and injection temperature were revised in November 2023, and the PROSPER results were updated to reflect the changes.

2.2 Material Selection

The materials for the CCS wells were selected based on resistance to corrosion. There is negligible corrosion for CO2 with low water content (<258 ppm), as the injected CO_2 does not form a separate aqueous phase. However, a very corrosive electrolyte forms when water precipitates out of the dense phase CO_2. Blade evaluated the solubility of water in dense phase CO_2 to determine how much water dense phase CO_2 can hold before water condenses. The effects of different impurities, temperature and pressure were considered in the analysis. Results show that presence of impurities lowers the solubility limit of water in dense phase CO_2. The solubility limit of water in dense phase CO_2 is clearly dependent on temperature and pressure of the system.

Thermodynamic modelling was used to establish and assess the environment inside the CCS well. The pH of the environment was estimated and corrosion resistance for different materials such as carbon steel, regular 13Cr, modified 13Cr, modified 17Cr, and 22Cr were determined. Various scenarios were considered, viz., corrosion due to injection alone, and corrosion when injected gas mixes with reservoir fluids. A sensitivity study was completed to determine the influence of impurities on the corrosion of materials and the pH of the environment. In addition, an extensive literature review was conducted, to confirm the results of the model. Results of analysis show that carbon steel will not withstand corrosion brought by any upset in the system such as water phase precipitation, since the corrosion rate of carbon steel in the aqueous phase is far greater than 10 milli-inches per year (mpy), based on the model and the data obtained in the literature. When wet injectate is unavoidable and water precipitates as second phase, modified 13Cr can be used. Both the model and the literature data show corrosion rates that are below four mpy for shut-in conditions and 1.3 for injection conditions (Figure 39).

Formation of elemental sulfur due to the presence of H_2S and O_2 were reported in the literature and may cause a further increase in the corrosion rate predicted by the models. If elemental sulfur is anticipated, further testing is recommended and nickel-based alloys or austenitic stainless steels such as Alloy 28 may be options.

The key conclusions from thermodynamic modeling and literature review are as follows:

- Liquid water (aqueous) phase may precipitate when the amount of water goes beyond the solubility limit. This may occur during upset conditions or shut-in conditions.
- Corrosion of materials in dense phase CO_2 undersaturated water is minimal, but corrosion in the liquid water (aqueous) phase formed from the injection stream is extremely high for carbon steel and 13Cr.
- Low carbon steels and standard 13 Cr grades exhibit alarmingly high rates of corrosion and are not recommended for use in the Aera CCS project.
- Modified 13Cr exhibits a corrosion rate of ~1.3 mpy during injection and ~3.7 mpy during shut-in conditions. 22Cr has the lowest corrosion rate during injection and shut-in (0.4 mpy) for the materials evaluated. Based on these rates, Modified 13Cr is a reasonable choice for material grade.
- Presence of elemental sulfur from the pre-combustion injection stream, and from the reaction of the impurities in the injection stream, may cause further increase in the corrosion rate predicted by the models, and may drive the selection of higher grades (such as 22 Cr). Proper assessment of the chosen alloy, either modified 13Cr or 22Cr, would require testing in the presence of sulfur to investigate corrosion and possibly cracking.

A detailed discussion of Material Selection is provided in Section 5. Table 22 shows a summary of materials recommendations for injection and observation wells.

2.3 Well Design Overview

Repurposed wells are being considered for use as CO_2 injection wells. The 9 in. and 8 1/8 in. production casing in existing wells was evaluated for injection well loads and found to be inadequate in burst strength to meet the design requirements. Design results for the 9 in. casing with nominal wall can be found in Section 14. The wells being considered were drilled in the 1930s and 1940s using non-API casing. Based on the design load analysis and the age of the wells, the recommendation is to install new inner casing with cement to surface which results in a well design that meets EPA Class IV requirements. The results presented in this report are based on repurposing wells with an inner casing.

The design results for several well types are summarized at a high level in this section with details in the body of the report. The objective of the well design analysis was to access the load conditions throughout the life of the injection well and make recommendations for the size, weight (wall thickness), and grade for the casing strings, liners, and tubing.

Well design analyses were performed for several well types that were proposed for this CCS project. The well types and details are specified in the design premise document *Aera CO_2 North Belridge Injection Wells Design DPD* [2]. Well types include repurposed wells and new drill wells. The proposed well design is based on the injection casing set above the injection zone, improving the chance of cementing the casing to surface which is a regulatory requirement. After the injection casing is set, an injection liner will be run and cemented through the injection zone. The completion design includes a tubing and packer as required by regulation for CO_2 injection.

The well design results were updated using the updated PROSPER results in November 2023.

Table 1 shows a summary the well types and design strings included in the design analysis.

Table 1: Well Types and Design Strings

Well Type	Design Strings
Repurposed with a cemented liner (based on well 9-1N)	• 7 in. inner casing set above the existing liner near the base of the Lower Santos Shale • 3 1/2 in. inner liner (wells with a 5 1/2 in. cemented liner) • 4 1/2 in. inner liner (wells with a larger OD cemented liner) • 4 1/2 in. tubing
Repurposed with an un-cemented liner (based on well 64-35N)	• 7 in. or 6 5/8 in. inner casing set near the existing casing shoe • 4 1/2 in. open hole liner • 4 1/2 in. tubing
New drill	• 13 3/8 in. surface casing • 9 5/8 in. intermediate casing • 7 in. casing set near the base of the Lower Santos Shale • 4 1/2 in. open hole liner • 4 1/2 in. tubing

2.3.1 Well Design Summary Results

Table 2 shows a summary of the well designs and proposed inner casings, liners, and tubing for the injection wells. Note that the 4 1/2 in. open hole liners are 12.6 ppf Modified 13Cr110 compared to the 4 1/2 in. 11.6 ppf Modified 13Cr80 tubing and cased hole liners.

Table 2: Injection Well Design Summary

Well	Existing Casing OD (in.)	Existing Liner OD (in.)	Proposed Inner Casing	Proposed Liner	Proposed Tubing

The well design results for each well type are summarized in a tabular format. The safety factors (SF) for critical and design loads are included in the tables. The SFs for all design loads are included in the body of the report.

The SFs in red font are less than the design factors (DF) that are specified in the DPD and in Section 6.1.1. As seen in the results, the stimulation load is a high burst load and governs many of the designs.

The summary results show the SFs for loads when the wall thickness is nominal and when the wall thickness is reduced because of corrosion. Cumulative wall loss was estimated for 25 years of service, based on the corrosion analysis results. Injection is assumed to end around year 25. RBW is the remaining body wall based on years of service. The burst SF is the ratio of the API burst strength to the burst load. The triaxial SF is the ratio of the minimum yield strength to the combined stresses created by the load conditions.

The Aera design factor for burst is 1.30. A typical industry DF for burst is 1.10. Where Aera's DF are not satisfied, the loads were evaluated using reliability based design. The triaxial design factor is 1.25.

Repurposed Wells Design Summary Results

Well 9-1N was evaluated as a representative well for the design of all repurposed wells. Table 38 shows the details for the 9-1N well design. Repurposed wells with an existing 9 in. casing and 7 in. inner casing well design similar to 9-1N can use the same design results. The design for repurposed wells also includes 6 5/8 in. inner casing for well 64-27N. The formation tops vary some among the repurposed wells but the loads are similar so the results are valid for all repurposed wells. The tables that follow show the SFs for some of the key pressure containing loads. The SFs for all design loads are included in the body of the report.

The proposed 7 in. inner casing design is an upper Section 1 with L80 grade casing and a Section 2 corrosion resistant alloy (CRA) casing on bottom. The top of the CRA section will be above the top of the confining layer.

The Section 1 inner casing design meets or exceeds all the load safety factors. Table 3 shows a summary of the 7 in. injection casing Section 1 safety factors.

Table 3: 7 in. 26 ppf L80 Inner Casing Section 1 Design Summary

Critical / Design Loads	Year	% RBW	Burst SF	Triaxial SF
6 Annulus operating pressure for injection 2,900 psi	0	87.5	2.34	2.50
9 Tubing leak shut in with methane to surface 3,950 psi	0	87.5	1.72	1.82
14 Stimulation tubing leak	0	87.5	1.40	1.54

Table 4 shows a summary of the inner casing design analysis for Section 2 including remaining body wall (RBW) because of possible corrosion wall loss in late life. SFs for all loads are shown in the body of the report. The inner casing cemented to surface is planned for isolating the existing production casing.

The design results from Table 3 and Table 4 will be used for all repurposed wells with 7 in. inner casing.

Table 4: 7 in. 26 ppf Modified 13Cr80 Inner Casing Section 2 Design Summary

Critical / Design Loads	Year	% RBW	Burst SF	Triaxial SF
6 Annulus operating pressure for injection 2,900 psi	0	87.5	2.34	2.50
	25	77.7	2.08	1.93
9 Tubing leak shut in with	0	87.5	1.72	1.82

Critical / Design Loads	Year	% RBW	Burst SF	Triaxial SF
methane to surface 3,950 psi	25	77.7	1.53	1.40
14 Stimulation tubing leak	0	87.5	1.40	1.54

Table 5 shows the summary of the tubing design analysis. The 4 1/2 in. tubing analysis is valid for the well types that have 4 1/2 in. tubing. The wells have similar setting depths for the packer and tubing. The design results from Table 5 will be used for all wells with 4 1/2 in. tubing. The stimulation load is not included in the summary table. It is assumed the stimulation treatment will use a frac string.

Table 5: 4 1/2 in. 11.6 ppf Modified 13Cr80 Tubing Design Summary

Critical / Design Loads	Year	% RBW	Burst SF	Triaxial SF
6 Injection Steady State 2,800 psi	0	87.5	2.69	2.73
	25	73.2	2.25	2.16
7 Shut-in tubing pressure with methane to surface 3,950 psi	0	87.5	1.97	1.98
	25	73.2	1.64	1.58

Table 6 shows the summary of the 3 1/2 in. inner liner design analysis. The 3 1/2 in. inner liner is an option for cementing inside existing carbon steel cemented liners to isolate the carbon steel liner from the CO_2.

Table 6: 3 1/2 in. 9.2 ppf Modified 13Cr80 Inner Liner Design Summary

Critical / Design Loads	Year	% RBW	Burst SF	Triaxial SF
5 Steady state CO_2 injection 2,800 psi	0	87.5	>3	>3
	25	73.5	>3	>3
10 Shut-in tubing pressure with methane to surface 3,950 psi	0	87.5	>3	>3
	25	73.5	>3	>3
9 Stimulation 5,000 psi	0	87.5	1.79	1.89

Table 7 shows the summary of the 4 1/2 in. inner liner design analysis. The 4 1/2 in. inner liner is a design for wells with existing cemented liners that can accommodate a 4 1/2 in. inner liner to isolate the existing carbon steel liner.

Table 7: 4 1/2 in. 11.6 ppf Modified 13Cr80 Inner Liner Design Summary

14 Stimulation tubing leak	0	87.5	1.44	1.58

New Drill Summary Results

The new drill well design includes the surface casing and intermediate casing. The details of the surface casing design are shown in Table 62 and the minimum safety factors are shown in Table 63. The details of the intermediate casing are shown in Table 62 and the minimum SFs are in Table 64.

The well design is 7 in. injection casing set near the base of the Lower Santos Shale with a 4 1/2 in. injection liner run and cemented through the injection zone. The completion is 4 1/2 in. tubing.

Table 62 shows the well design details for the new drill wells.

The 4 1/2 in. tubing design results are the same as Table 5.

Table 10 shows the summary of the 7 in. casing design analysis for Section 1.

Table 10: New Drill 7 in. 26 ppf Modified 13Cr80 Section 1 Casing Design Summary

2.3.2 Collapse Load Analysis

Collapse loads for the tubing, casing, and liners as described in the DPD were evaluated as part of the well design analysis. The DFs for collapse are included in the body of the report. It is typical for the collapse to meet the design factor when the pipe is new and has the nominal wall thickness and a full evacuation load is assumed. However, when reduced wall thickness because of corrosion is assumed, the collapse SF can be reduced to less than the DF. An argument can be made that full evacuation and even 50% evacuation is not a valid assumption for late life loads for CCS wells where the reservoir pressure is increasing because of CO_2 injection. Therefore, it is reasonable to assume the full evacuation collapse SF is a design check rather than a design requirement. Based on this, the collapse requirements for the casing, liners, and tubing are met in early life and late life collapse safety factors are reported for information.

2.3.3 API RP 90-2 MAWOP

Maximum allowable wellhead operating pressure (MAWOP) analysis for the well design with 7 in. casing and 4 1/2 in. tubing meets the requirements for 2,900 psi annulus pressure.

Additional details of API RP 90-2 analysis are included in Section 6.11.

2.3.4 Evaluation of Corrosion and Wall Thickness on Well Designs

CCS well design requires an evaluation of the casing, tubing, and liners during and at the end of the injection phase, where the well has been in injection service and the BHP and burst loads on the well tubulars are increasing with time and reach the maximum pressure at the end of the injection phase. The corrosion wall loss and the pressure are therefore at their highest at the end of the injection phase. This is different from oil and gas well designs where the maximum loads occur at the beginning of the well life and the tubulars are newly manufactured to API specifications.

The modeling results for corrosion wall loss vs. time for 25 years of service are summarized in Section 6.3.

2.3.5 Casing and Tubing Connections

Connections with a metal-to-metal seal and 100% pipe body strength are recommended for the new injection casing, tubing, and liners planned for the repurposed wells and new drill wells. If reduced OD connections are needed because of tight clearances, the tension and compression safety factors should be checked. API connections are adequate for the drilling casing for the new drill wells. The number of connections for the new tubing, liner, and casing is relatively small and the additional cost for high quality connections can be justified by having long term injection wells with a low risk of a connection leak.

2.3.6 Annular Pressure Management

Class VI requirements include maintaining tubing × casing annulus pressure higher than the tubing injection pressure. The implication of this requirement is that an annulus pressure management (APM) system must be included, to maintain the annulus pressure within a range that also considers changes in the annulus fluid temperature during injection and shut-in conditions. A discussion of APM is included in Section 6.14.

3 Introduction

The Aera North Belridge CCS project will permanently sequester CO_2 in the depleted 64 oil sands. It is planned to inject up to 1.6 million Mt (metric tons) per year when the project is completed. The field has many existing wells, with some of the wells drilled in the 1930s and 1940s. The 64U and 64W zones have been produced for decades, and the current reservoir pressure is around 700 psi. Water injection has been used in the field, implying that water may be present in the sands. Other zones including the Temblor sands are hydrocarbon bearing. The 64 sands are the target sequestration zone. The Lower Santos Shale immediately above the 64U sand is the primary confining layer. The Agua sands zone is the dissipation layer. Figure 1 shows the generalized North Belridge Field stratigraphy. The field structure is an anticline oriented north-west to south-east. Figure 2 shows the field structure map and a cross section.

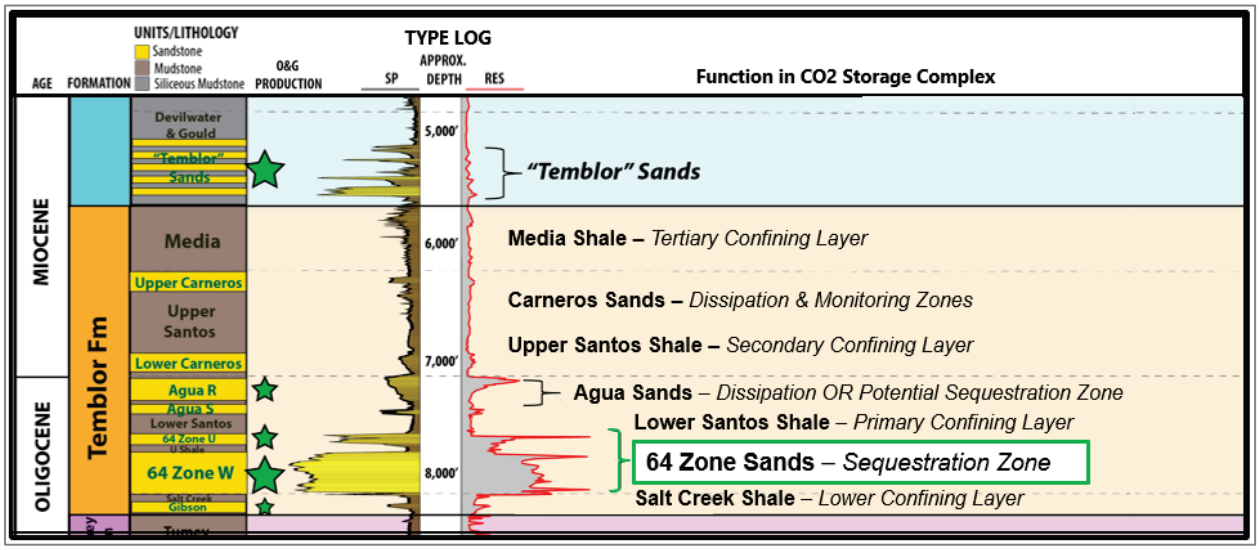

Figure 1: North Belridge Stratigraphy

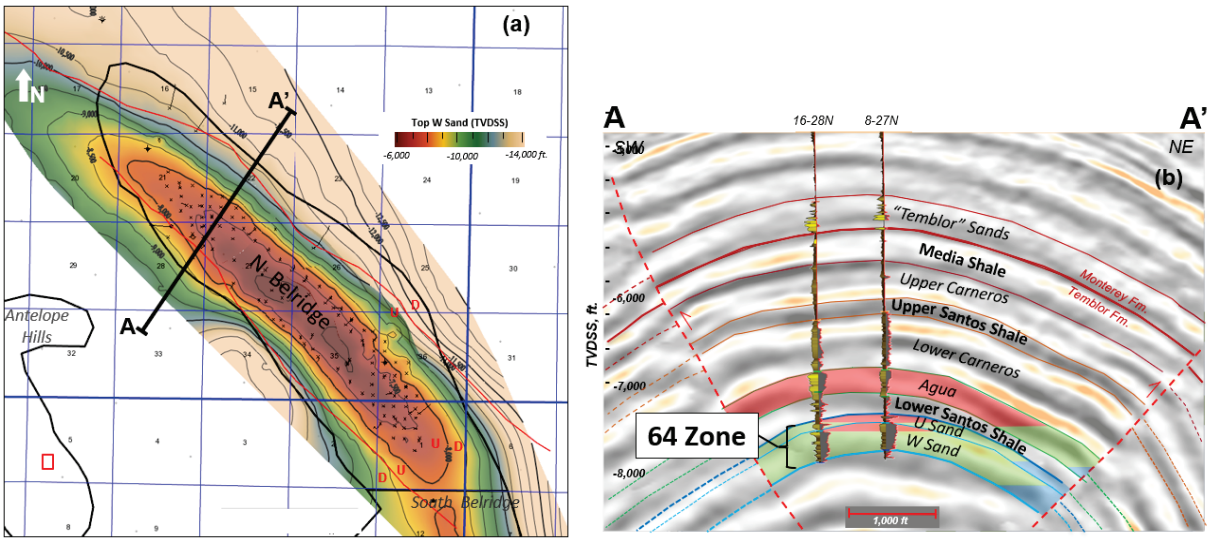

Figure 2: North Belridge Structure Map (a) and Cross Section (b)

Preparation of permit applications for the repurposed wells and new drill wells is in progress. Five existing wells are being considered for repurposing to injection wells. The current list of wells planned for repurposing as injectors is as follows:

- 9-1N
- 64-35N
- 64-27N
- 55-26N
- 27R-27N

Blade was contracted by Aera to conduct this FEED study including well performance and flow assurance, materials selection, and corrosion analysis, and well design for repurposed injection and new drill wells. The FEED study was performed using Blade's rigorous, multidisciplinary FEED process for CCS projects. The work was done in mid-2022 and updated in November 2023.

This report includes the details of the study, technical approach, analysis, results, conclusions, and recommendations. The input data and assumptions are included in the DPD [2]. The report is organized as follows:

- Section 1 is an executive summary
- Section 2 summarizes the key conclusions and recommendations
- Section 3 is an introduction to the work
- Section 4 includes details of the well performance and flow assurance analysis. The results of this work were used in the well design analysis to define the pressure and temperature profiles for tubing and casing loads, and to define conditions for materials selection and corrosion rate. CO_2 injectivity for three wells was evaluated, an injection test was developed, and injection modeling was performed to support Aera reservoir simulation modeling.
- Section 5 covers the materials selection and corrosion analysis. Expected corrosion rates and recommended tubular grades are the main outcome of this section.
- Section 6 presents a detailed treatment of the well design and analysis. The results of the previous two sections were used to perform design checks of the various tubulars for both new drills and repurposed injectors. Corrosion rates from the materials selection study were considered in establishing well integrity for the life of injection. High-level procedures for conversion of existing wells into CO_2 injectors are included in the DPD. Cement recommendations are also included in this section.
- Several appendices are included with design data and additional information and details.

The findings of this study are expected to guide the permitting and detailed well engineering, well construction, and CCS operations in the field.

4 Well Performance

Well performance and flow assurance analyses were performed using Petroleum Experts PROSPER application. CO_2 is a unique gas in that its PVT (Pressure Volume Temperature) behavior differs from an oil or gas stream, and its unique behavior determines the well performance. Petroleum Experts specifically developed an EOS (Equation of State) model for a CO_2 stream with and without impurities. For other clients, Blade has validated the Petroleum Experts EOS model results to field data, and Blade therefore recommends PROSPER for well performance studies for CO_2 streams in this work.

4.1 Defining PROSPER Well Models for CO_2

The goal of a well model is to aid in the determination of the appropriate tubing sizes to meet the project CO_2 sequestration objectives. For more than eight years, Blade has utilized Petroleum Experts software. Blade has validated the software and its PVT models across a variety of CO_2 stream compositions for multiple clients.

Understanding CO_2 wells means understanding that although CO_2 is a gas, its flow characteristics are unlike traditional gas wells. CO_2 flow and phase are sensitive to pressure like gas wells, and more sensitive to temperature than gas wells. Figure 3 shows the phase diagram for a pure CO_2 stream, a CO_2 stream with 4% N_2, and a CO_2 stream with 4% CH_4. CO_2 streams from anthropogenic sources are likely to be nitrogen dominate, and CO_2 streams from the processing of hydrocarbons are likely to be methane dominate. Pure CO_2, shown in black as a single line, goes directly from liquid to gas and gas to liquid. The addition of impurities opens the phase envelope where both gas and liquid phases coexist. The addition of impurities shown decreases the supercritical temperatures and increases the supercritical pressures. This study focuses on the PVT changes due to any impurities as it affects flow.

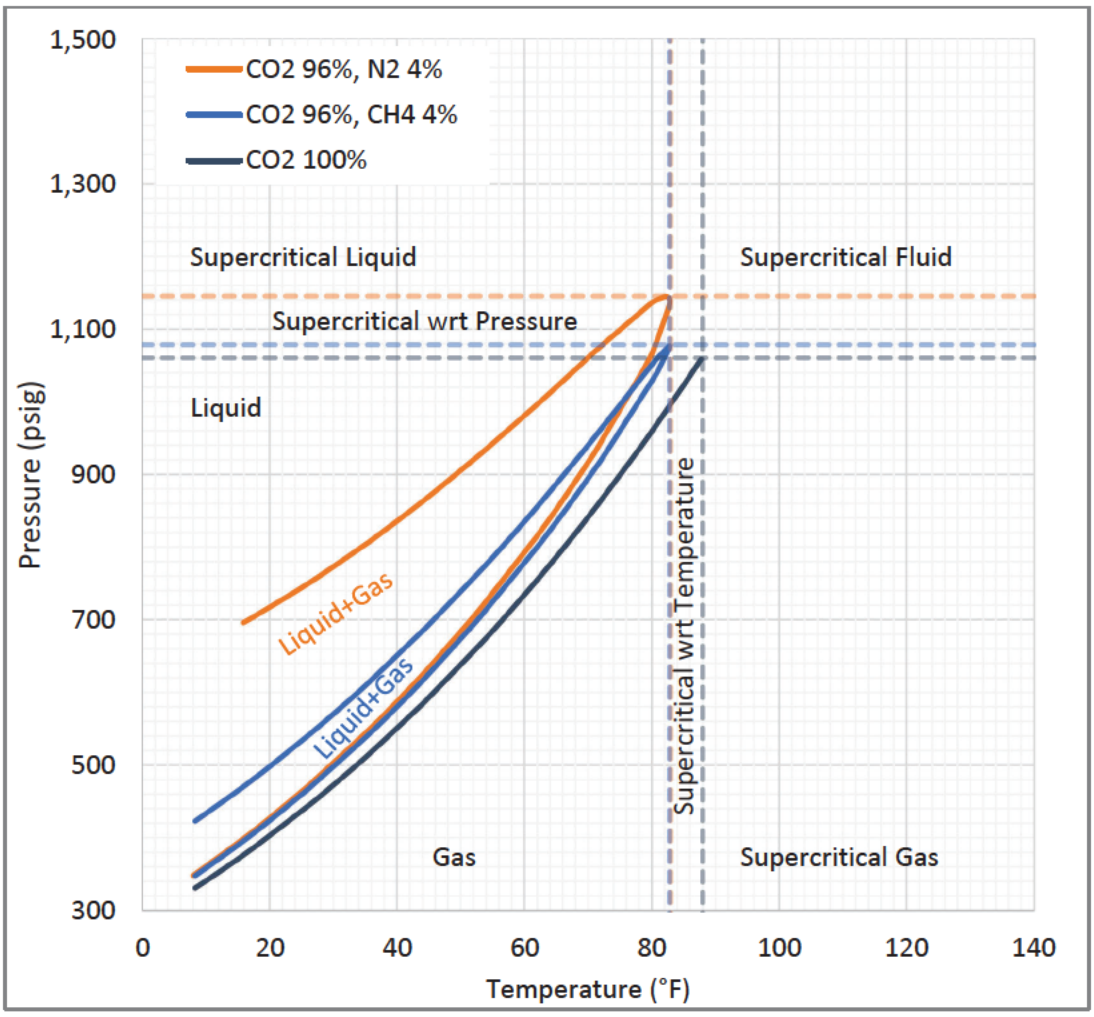

Figure 3: CO_2 Phase Diagram

Typical CO_2 transport lines maintain a minimum pressure such that the stream flows as a supercritical fluid to maximize density and minimize pipeline sizes. Minimizing impurities reduces the minimum line pressure for transport.

Well injection is best if the flow temperature and pressure conditions from the wellhead to the bottomhole do not cross the phase boundaries. Injection becomes unstable when crossing the phase boundary. Pseudo-steady state well performance applications, such as PROSPER, can be misleading in that they calculate an averaged well response, and the well can be more unstable than predicted as slugs vary in time. The difficulty will lie with facilities that have to manage varying injection rates with too great a rate variance. Blade has worked for clients where the design of facilities did not manage the swings, and the client shut down the operations.

For this initial study, exact facility delivery conditions were not available. Therefore, this study held the minimum injection temperature at 94°F to avoid the phase boundary issue. The reservoir pressure is well below the critical pressure and hence pressure control was not possible. Designing the CO_2 sequestration network with facilities and wells would enable a detailed study of operating conditions to keep injection stable. Note that this stability does not affect the wellbore design but affects the operation of the injection network. For example, the facilities network may deliver the CO_2 stream to the injection manifold for the wells at a temperature and pressure not optimal for injection. This work

assumes the optimal conditions at the wellhead for injection. Optimal field operation is an issue for later.

Figure 4 shows how the PROSPER density plot of CO_2 sequestration stream can change versus pressure for various temperatures. In this figure, the lower the temperature the higher the density (PROSPER set each line to the same line and marker). At sub-critical pressures (1,000 psig and lower), the density of the injection stream varies minimally with respect to temperature, and the CO_2 stream behaves more like a normal gas stream. The CO_2 stream becomes liquid-like as the pressure increases.

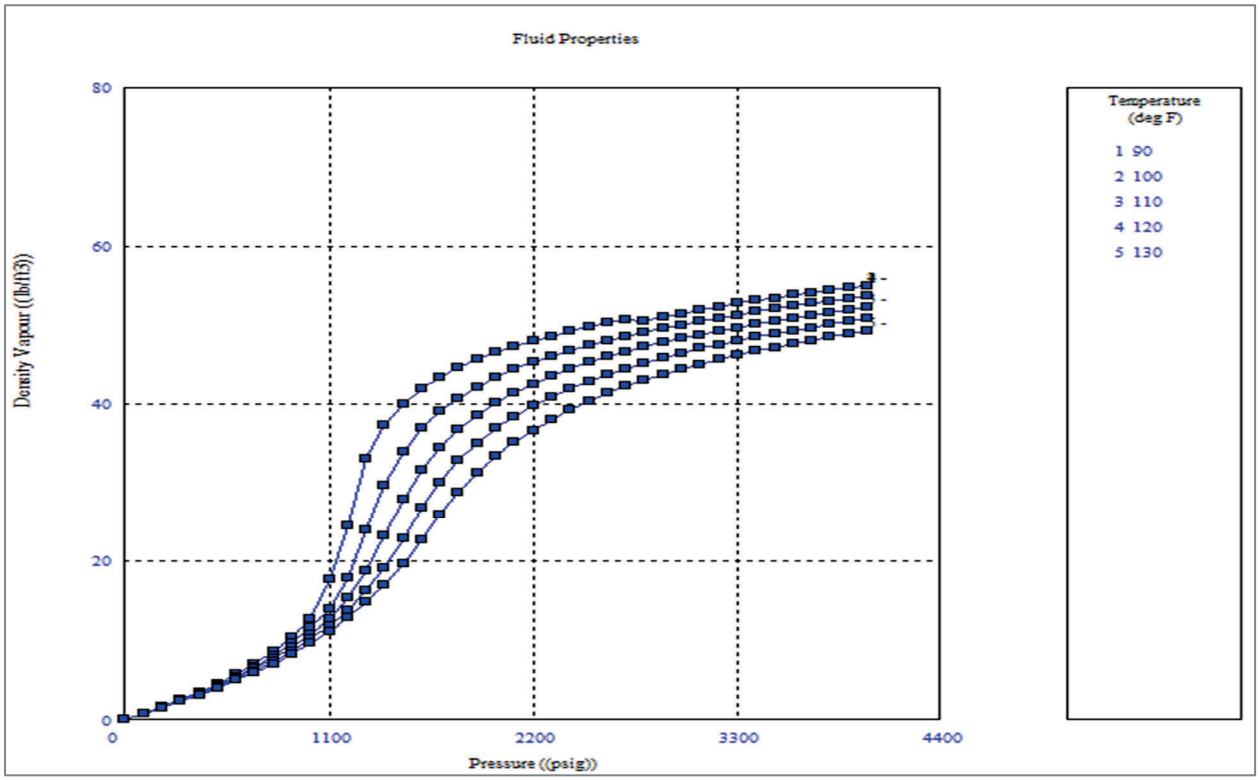

Figure 4: Pure CO_2 Density versus Pressure at Possible Injection Temperatures

This wide variance of density leads to operational situations not found with traditional gas or liquid wells. The tubing size must flow a constant mass rate of injection per day over its life. This means:

- At sub-critical conditions, the injection stream flows more gas-like and benefits from larger tubing.
- At super-critical conditions, the injection stream flows more liquid-like and can use smaller tubing.

Well performance models in PROSPER can assess the wells under expected pressure, temperature, and rate conditions. The steps to build the well models were as follows:

1. The fluid method must always be Equation of State rather than Black Oil.
    a. Blade recommends the Peng Robinson EOS which is the default EOS in PROSPER. The other is Soave Redlich Kwong. The Peng Robinson recommendation is based on successful matching for a large amount of field data.
    b. Blade recommends using the volume shift for full composition and to correct CO_2 density. Blade learned through personal communication with Petroleum Experts that they contracted Heriot Watt University to conduct laboratory PVT experiments for various CO_2 compositions. These

experiments formed the basis of the CO_2 corrections to the equation of state model in Petroleum Experts software.

c. Define the composition. A CO_2 stream is typically CO_2 dominant with select impurities such as N_2 and CH_4. The stream is typically gaseous components with no condensate or liquid components that form at injection temperatures and pressures. Input simple CO_2 streams directly into PROSPER, and let it fill in the table as PVT matching is not typically necessary.

d. Do not enter water into the CO_2 stream composition. Use the water to gas ratio to account for the water.

e. Model only the CO_2 stream components that are of high enough mole percent to affect the PVT outputs, such as viscosity and density. Conduct separate corrosion studies.

2. The inflow model is the resistance to injection, and the key is to match the resistance at points in time over the injection life of the well.

   a. All inflow models require a reservoir or layer pressure. The pressure input should be the injection area average pressure. As CO_2 injection proceeds and the CO_2 plume spreads from the wellbore, it is the average pressure of this plume that is the resistance. The initial pressure can be the reservoir pressure, and the final pressure remains below fracturing pressure. The design considers the initial and final pressures and selected pressures in between. The progression in time between the initial and final pressure is outside the scope for this work. If modeling facilities are required, it is necessary to determine wellhead injection pressures over time, and this requires the injection area average pressure progression in time that reservoir simulation can solve.

   b. This work used Darcy-based inflow models with permeability as the resistance factor. These models are based on net permeability thickness, and it is the CO_2 effective permeability to the reservoir conditions at a time point of interest. For instance, the permeability is highest if the reservoir is gas-saturated, and the permeability is the lowest if the reservoir is water saturated. This effective permeability can change in time. The importance of effective permeability is dependent on the CO_2 injection requirements of a well. Greater injection pressure can always be low permeability, but that may conflict with facilities requirements and fracture initiation pressure.

3. The equipment data should reflect the repurposed or new well.

   a. The well's deviation survey.

   b. The downhole equipment along the injection flow path.

   c. The geothermal temperature gradient. Temperature is more important for CO_2 flow than oil, gas, and water flow. Hence, do not simplify this gradient.

   d. Overall heat transfer coefficient along injection flow path. A rule of thumb for dry and wet gas is 1 to 3 BTU/hr.ft^2.°F. For multiple clients where Blade has matched against measured flowing gradients, a rule of thumb for CO_2 flow is 1.5 BTU/hr.ft^2.°F.

4. The downflow/upflow model selected must always be mechanistic—never use a correlation. Mechanistic models account for the fundamentals of flow while correlations are for specific fluids where none of the fluids were CO_2.

4.2 64-Zone Well Match and Injectivity Model

The Belridge 64-Zone wells have limited data to determine injectivity. Aera presented five wells with the best available data. A well match and injectivity analysis was performed for these wells, to provide a basis for repurposed CO_2 sequestration wells.

- 64-35N, detailed match of three-point test for injectivity, detailed injectivity study
- 64-27N, match of three injectivity tests, injectivity study
- 63-35N, not sufficient data for matching inflow model, no injectivity study
- 51-35N, not sufficient data for matching inflow model, no injectivity study
- 49-35N, match of injection points, injectivity akin to 64-35N

The injectivity modeling includes the facility delivery conditions to well conditions, and on to reservoir conditions:

- Facilities
  - Minimum delivery pressure—pipelines typically deliver above supercritical conditions (if the injection wellhead pressure is below critical, the delivered gas is typically choked at the field to reduce to injection pressure which also reduces the temperature).
  - Maximum delivery pressure determined from reservoir and well
- Well
  - Repurposed existing wells with limit to tubing ID
  - Minimize friction for project rate within facility constraints
- Reservoir
  - Permeability Resistance: relative permeability to CO_2 affected by fluids previously in formation
  - Pressure Resistance: Injection area average reservoir pressure over time

Injection of CO_2 forms a plume around the well that becomes the resistance to injection. The average injection area pressure of the plume is the pressure to model rather than the average reservoir pressure of the entire reservoir. This work models the injection by varying the average injection area pressure. Modeling the plume growth in time requires reservoir simulation and is outside the scope of this work.

The well injection of CO_2 into the reservoir depends on the state of the reservoir around the well:

- If the reservoir is depleted gas, the relative permeability to CO_2 is high.
- If the reservoir has been invaded by water, the relative permeability to CO_2 is low and depends on the water saturation.

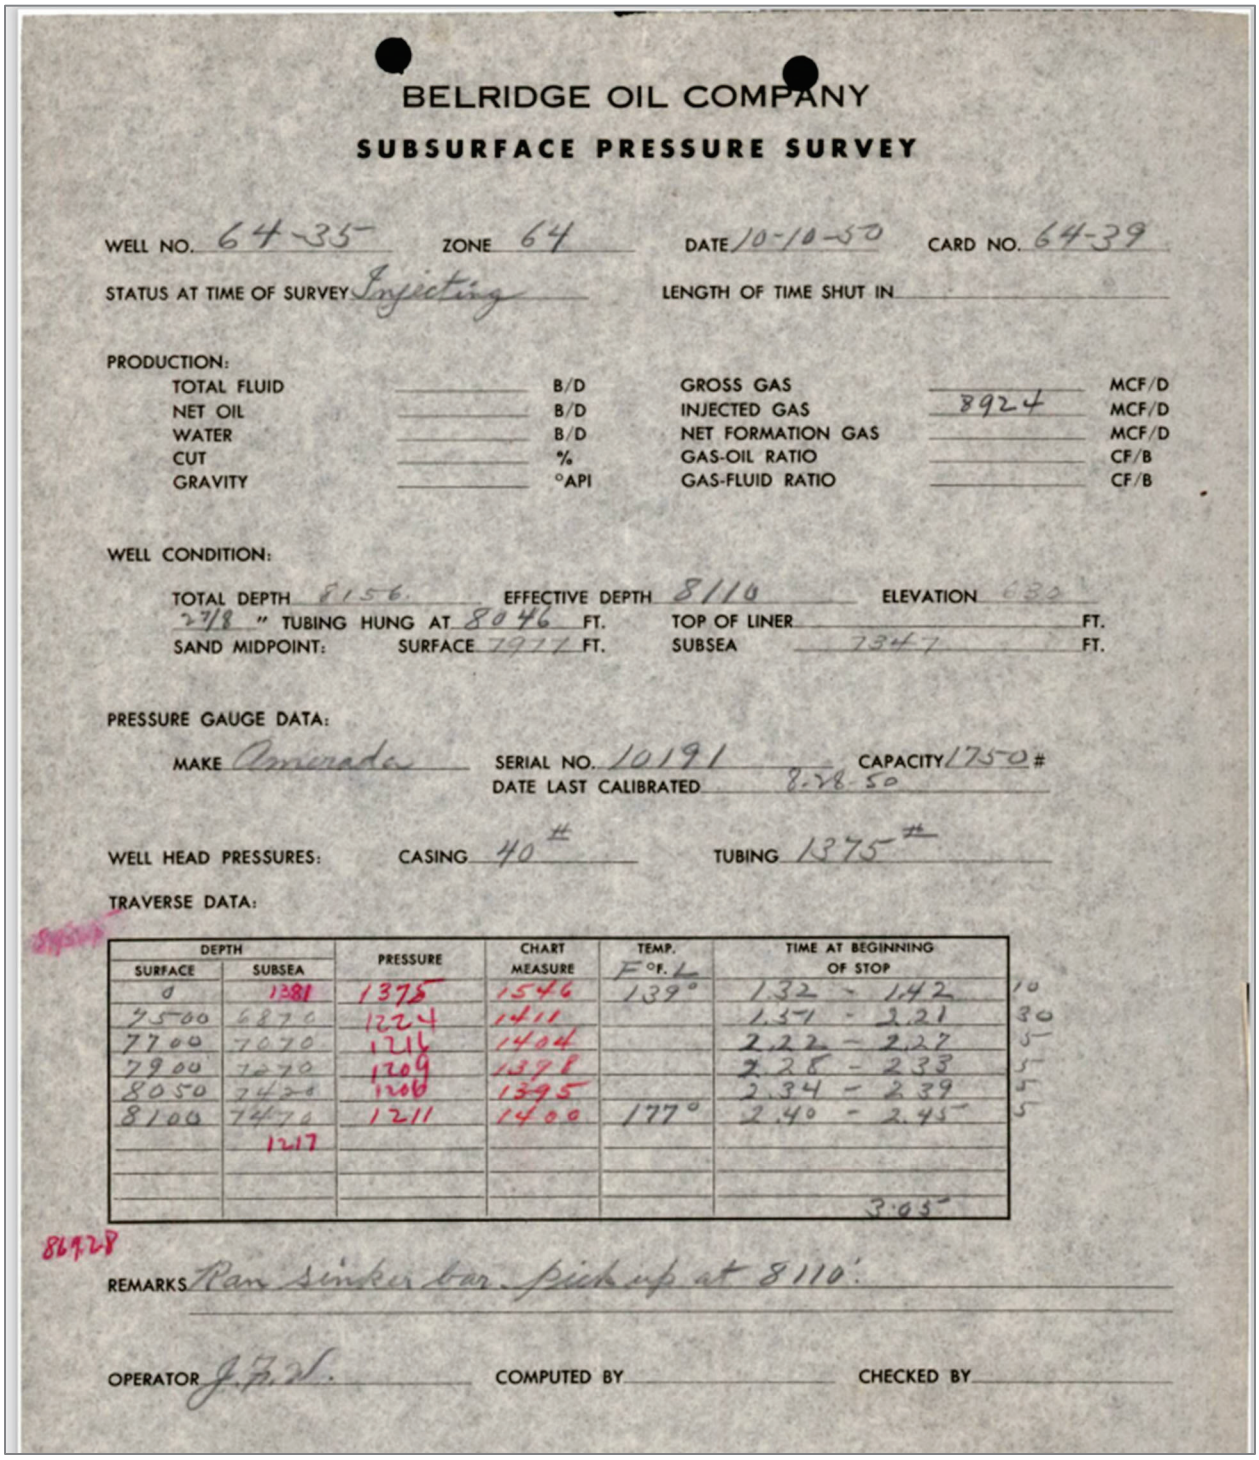
4.3 Well 64-35N Match and CO_2 Injectivity Study

This section first presents the 64-35N well match, and secondly presents the injectivity study.

4.3.1 Well 64-35N Match

The task and available sources for building the PROSPER well model were:

- Built well model per pressure survey of 1950—Figure 5 shows the original data
- Built inflow model per injection test of 1980—Figure 6 shows the original data
- Checked shut-in survey and flow test of 1940—Figure 7 shows the original data



The match of the injectivity test of 1980 converted the wellhead pressures to bottomhole pressures for the match. Table 13 lists the converted pressures, and Figure 8 charts the analysis. Based on wellhead pressures, the original analysts considered the second flowing point bad, but converting to bottomhole pressures indicates it's more likely that the third flowing point is bad. For this type of analysis, the permeability thickness and skin cannot be uniquely separated. Either a skin is assumed, and the permeability thickness determined, or the permeability thickness is assumed, and the skin determined. Figure 8 shows possible solutions to be:

- kh = 3,700 mD.ft with s = 0
- kh = 4,600 mD.ft with s = 2

Figure 9 shows a typical 64 W sand layered model with a total permeability thickness of 5,200 mD.ft. The Type 1 and Type 2 rocks have the highest permeability and will contribute more to the flow than the lower permeability zones. A layered model built per Figure 9 shows that the Type 4 rock essentially does not contribute, and that Type 3 rock contributes only a few percent of total flow. This shows that analysis of the three point test is in alignment with the most recent field model.

Figure 7: 64-35N Source Data: Shut-In Survey and Flow—Test 1940

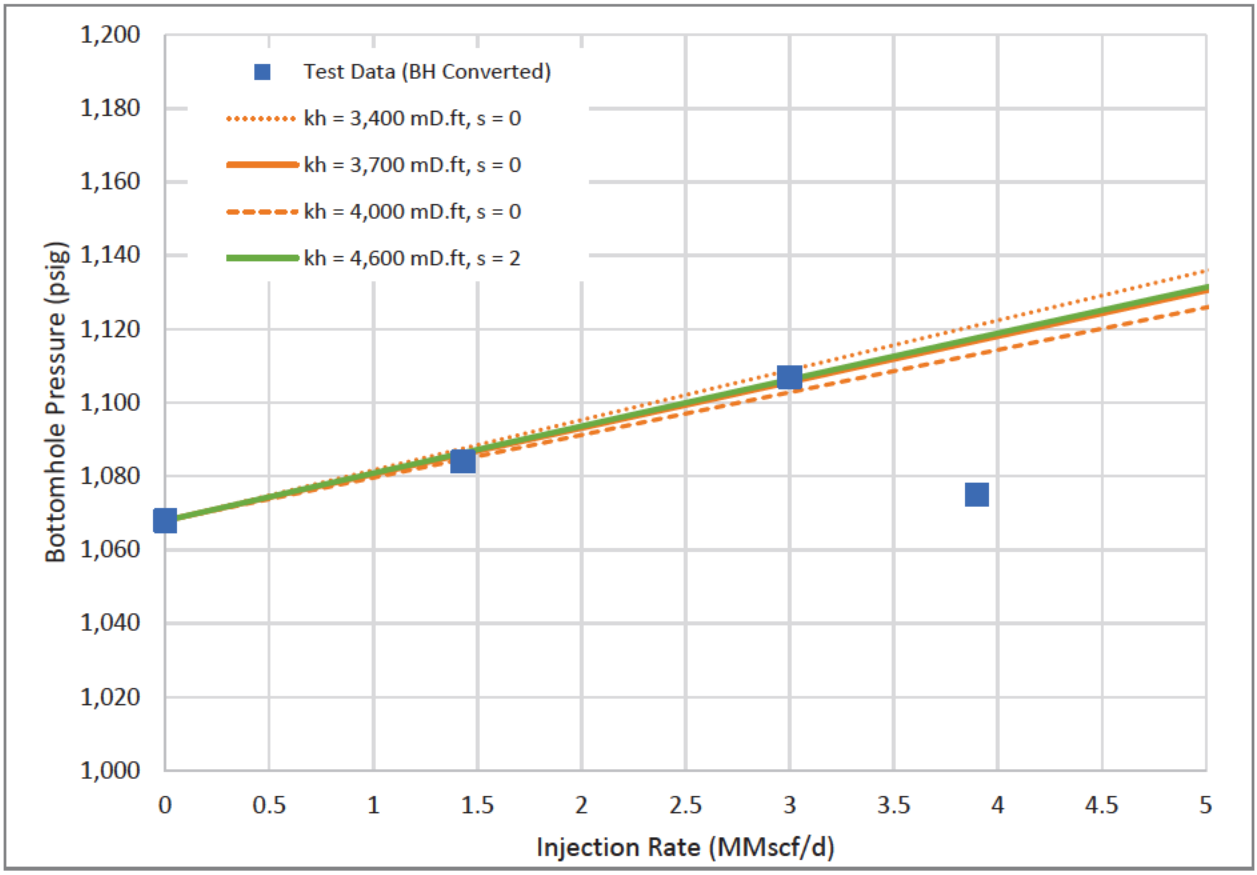

Figure 8: 64-35N: Matched Three Point Injection Test—1980

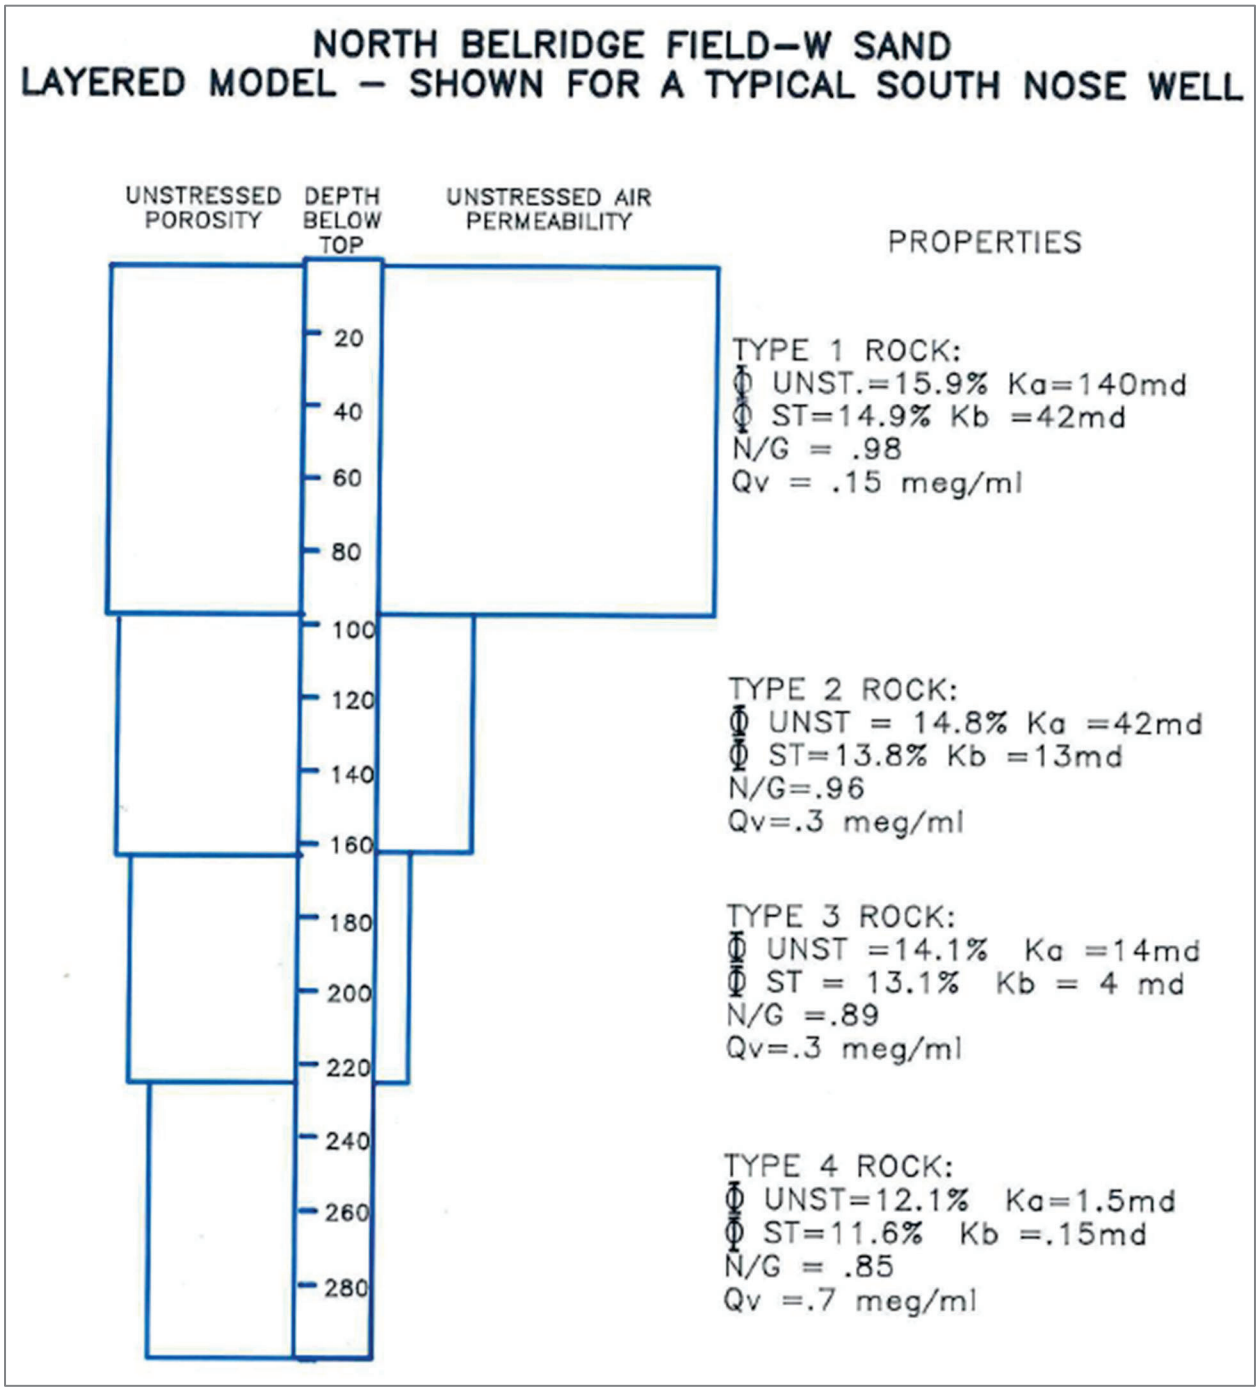

Figure 9: 1986 Belridge_64_Dev_engineering_Review.pdf

Figure 10 shows the match from the 1980 test applied to the shut-in and flowing test from 1940. The 1940 shut-in determines the reservoir pressure. The flow test had measured gas-rate and pressure at the wellhead. A flowing gradient model determined the bottomhole pressure, and a shut-in gradient model determined the wellhead pressure. The match of the two gradients indicates the match from 1980 is valid, and furthermore indicates there was no increase in wellbore skin over 40 years.

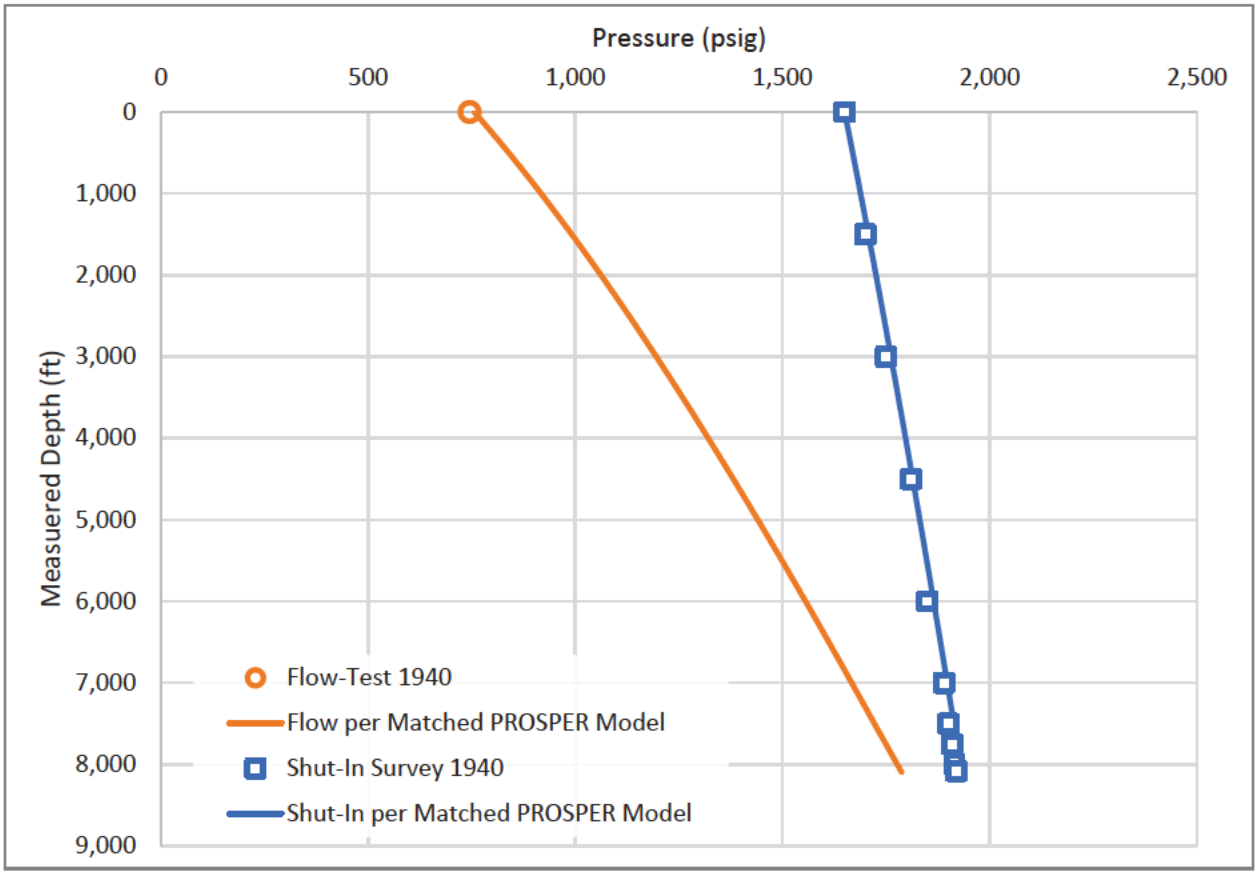

Figure 10: 64-35N: Shut-In and Flow Test—1940

4.3.2 Well 64-35N CO_2 Injectivity Study

An injectivity study was performed for different tubing sizes, with the following assumptions:

- Permeability thickness: kh = 3,700 mD.ft
- Skin: 0
- Tubing sizes: 2 7/8, 3 1/2, 4 1/2, and 5 1/2 in. (sizes that can be installed in well)
- Average injection-area pressures: 700, 2,000, and 3,500 psig
- Injection stream temperature: 90 °F

Figure 11, Figure 12, and Figure 13 show the required well injection stream pressure versus injection stream rate for the different tubing sizes at 700, 2,000, and 3,500 psig respectively. Conclusions are:

- 2 7/8 in., the original tubing size, leads to excessive friction that wastes compression
- 4 1/2 in. yields a good injection rate range with reasonable friction
- 5 1/2 in. yields minimally less friction pressure at the anticipated injection rate, and it is not necessary unless those rates per well were to increase.

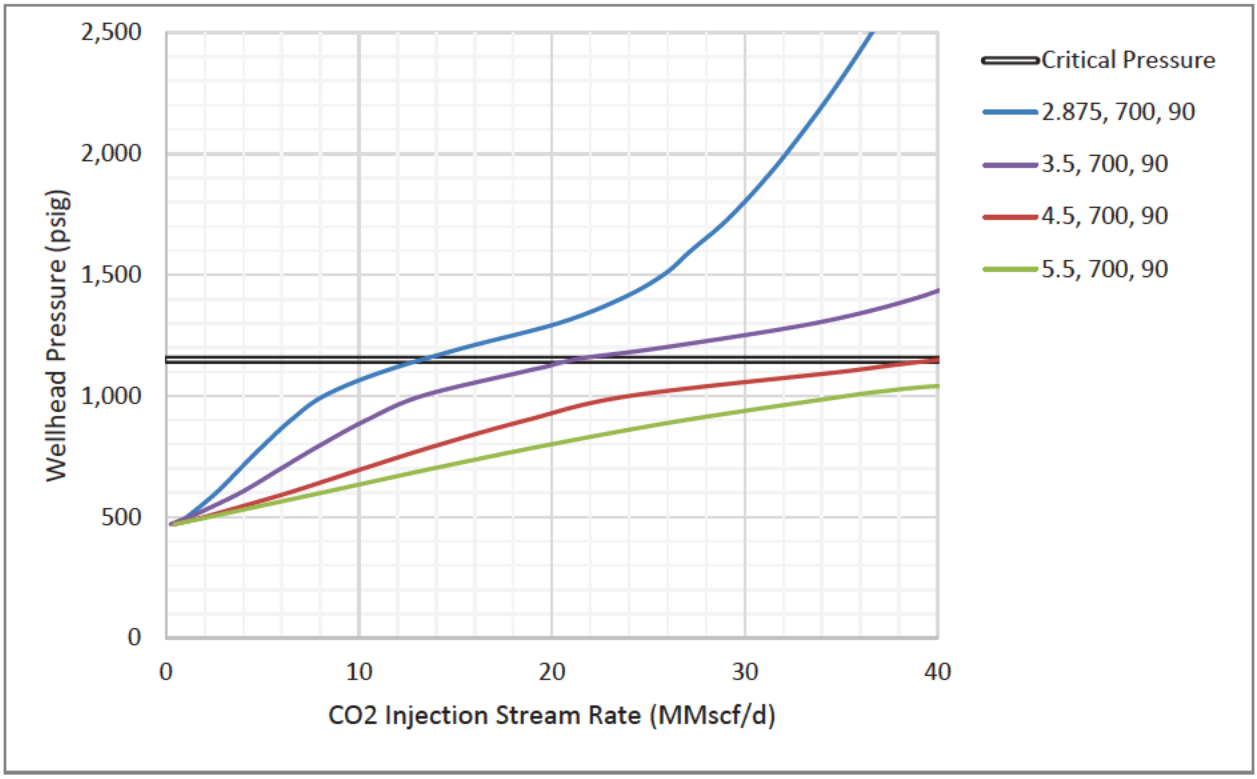

Figure 11: 64-35N CO_2 Injection: Tubing Sensitivity at Pavg = 700 psig, Tinj = 90°F

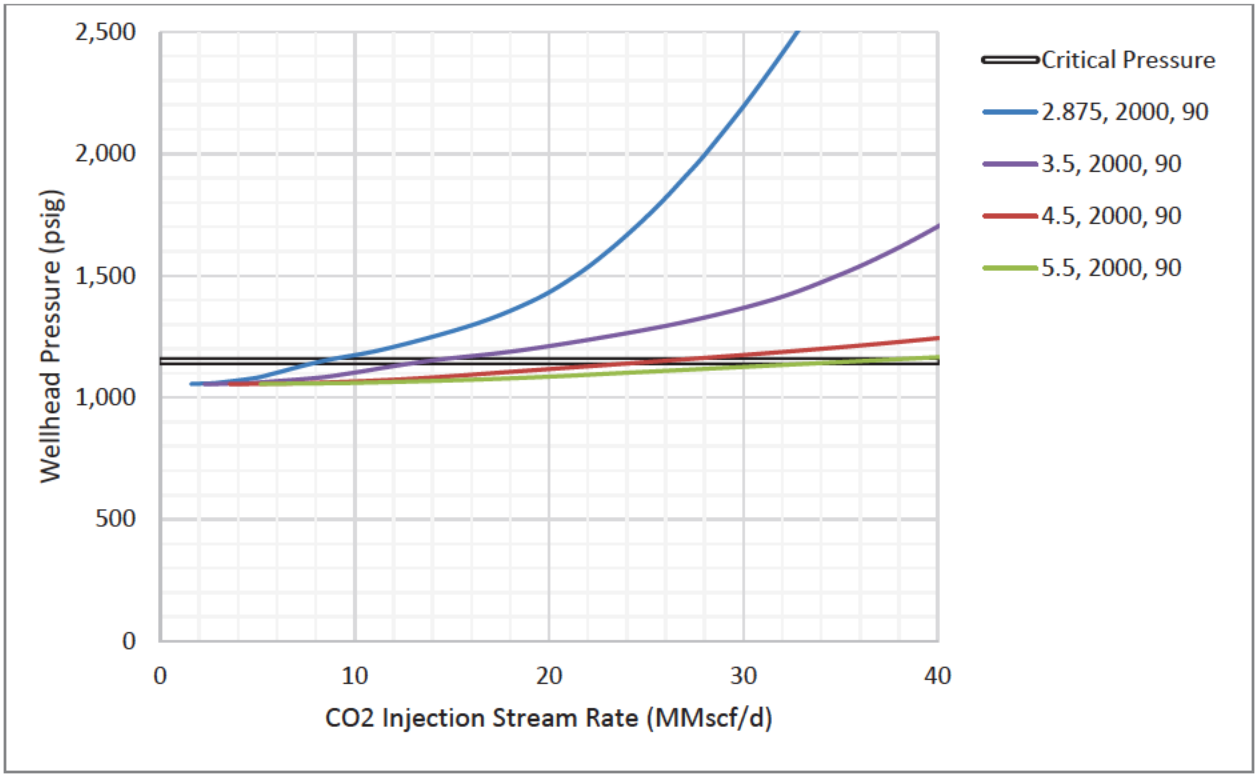

Figure 12: 64-35N CO_2 Injection: Tubing Sensitivity at Pavg = 2000 psig, Tinj = 90°F

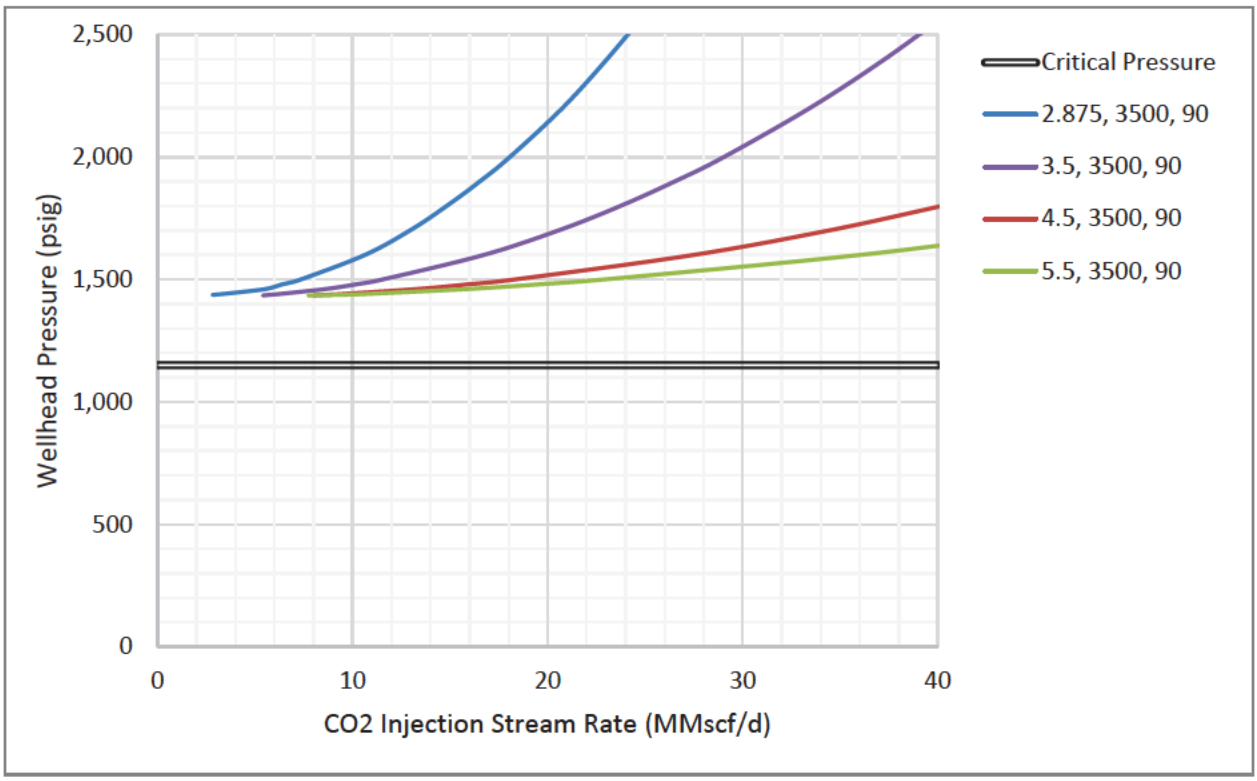

Figure 13: 64-35N CO_2 Injection: Tubing Sensitivity at Pavg = 3500 psig, Tinj = 90°F

An injectivity study reviewed injection temperatures with the following assumptions:

- Permeability thickness: kh = 3,700 mD.ft
- Skin: 0
- Tubing size: 4 ½ in.
- Average injection-area pressures: 700, 2,000, and 3,500 psig
- Injection stream temperatures: 70, 90, and 110°F

Figure 14 shows the required well injection stream pressure versus injection stream rate for the different injection temperature and average pressures. Conclusions are:

- Wellhead pressure requirements, hence, compression, are greater with increasing temperature. It is therefore necessary to balance compression costs versus cooling costs.
- Cooling the injection stream increases the minimum stable injection rate for the well
  - For example, if the reservoir pressure is 3,500 psig, an injection stream at 70°F must inject at least 10 MMscf/d, whereas an injection stream at 110°F can inject at any rate
  - Cooling the injection stream greatly minimizes the wellhead pressure required
  - But use caution when cooling below 90°F at a reservoir pressure of 2,000 psig or less because flow in the wellbore could cross the phase envelope and cause flow instabilities

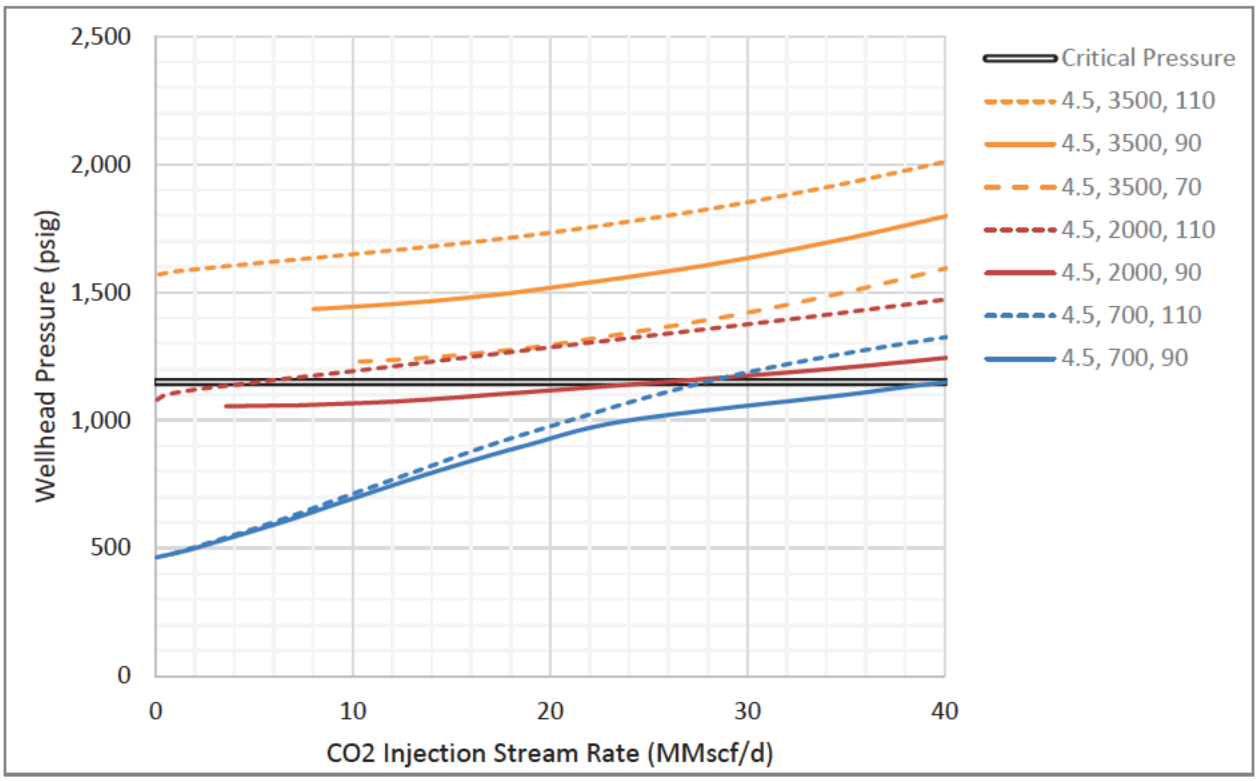

Figure 14: 64-35N CO_2 Injection: Injection Temperature Sensitivity

An injectivity study reviewed relative permeability with the following assumptions:

- Permeability thicknesses:
  - kh = 370 mD.ft — CO_2 rel perm reduced in presence of water
  - kh = 3,700 mD.ft — CO_2 rel perm highest if gas cap only
- Skin: 0
- Tubing size: 4 1/2 in.
- Average injection-area pressures: 700, 2,000, and 3,500 psig
- Injection stream temperature: 90°F

Figure 15 shows the required well injection stream pressure versus injection stream rate for the permeability thicknesses. Conclusions are:

- At kh = 3,700 mD.ft, a reasonable average injection rate is 30 MMscf/d
- At kh = 370 mD.ft, a reasonable average injection rate is 10 MMscf/d

The presence of water around the wellbore will reduce the relative permeability to CO_2 and decrease the injectivity into a well. This will require more wells to meet the same field injection target. This may be an issue since the 64-zone has been used for water disposal. This is one of the reasons that an injectivity test in the field is recommended (see section 4.6).

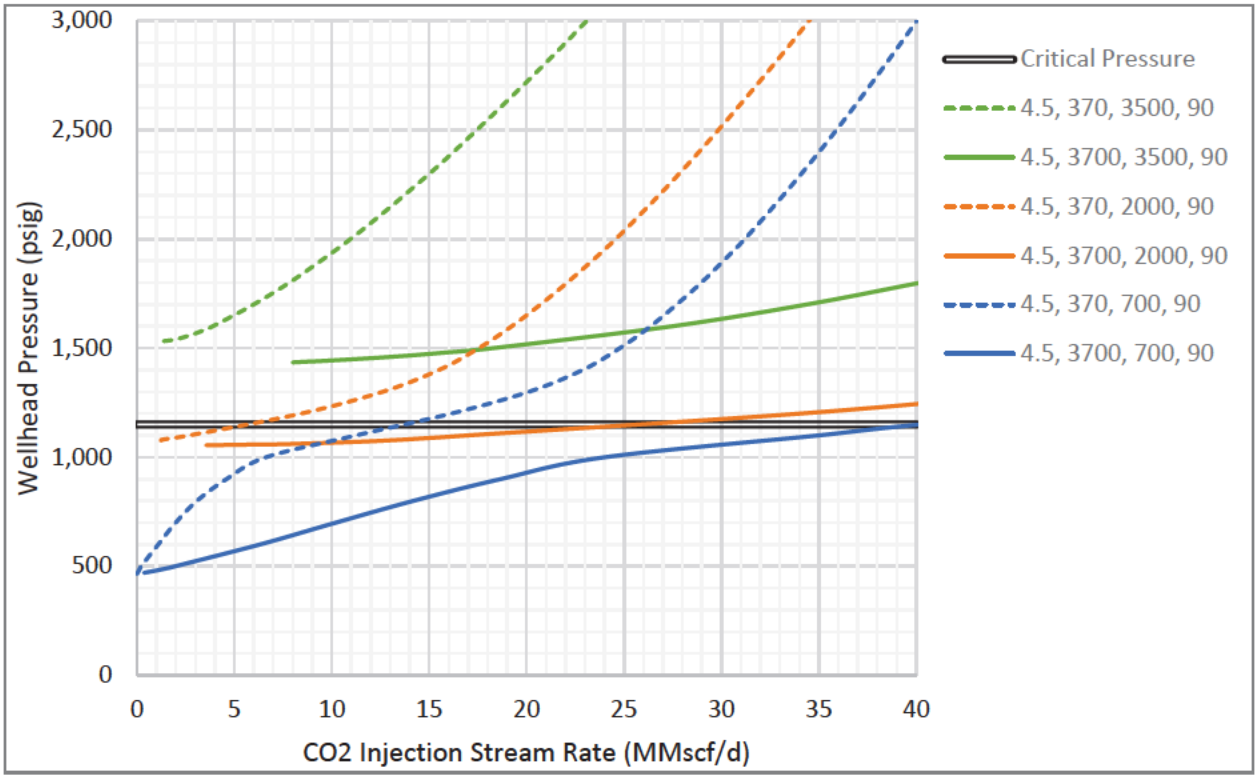

Figure 15: 64-35N CO_2 Injection: Permeability Thickness Sensitivity

A drop in relative permeability lowers the injectivity which then may lower the optimum tubing size from 4 1/2 to 3 1/2 in. An injectivity study reviewed this change with the following assumptions:

- Permeability thicknesses: kh = 370 mD.ft and 3,700 mD.ft
- Skin: 0
- Tubing sizes: 3 1/2 and 4 1/2 in.
- Average injection-area pressures: 700, 2,000, and 3,500 psig
- Injection stream temperature: 90°F

Figure 16 and Figure 17 show the required well injection stream pressure versus injection stream rate for the permeability thicknesses. Conclusions are:

- 3,700 mD.ft is best with 4 1/2 rather 3 1/2 in. tubing
- 370 mD.ft is best with 3 1/2 rather 4 1/2 in. tubing

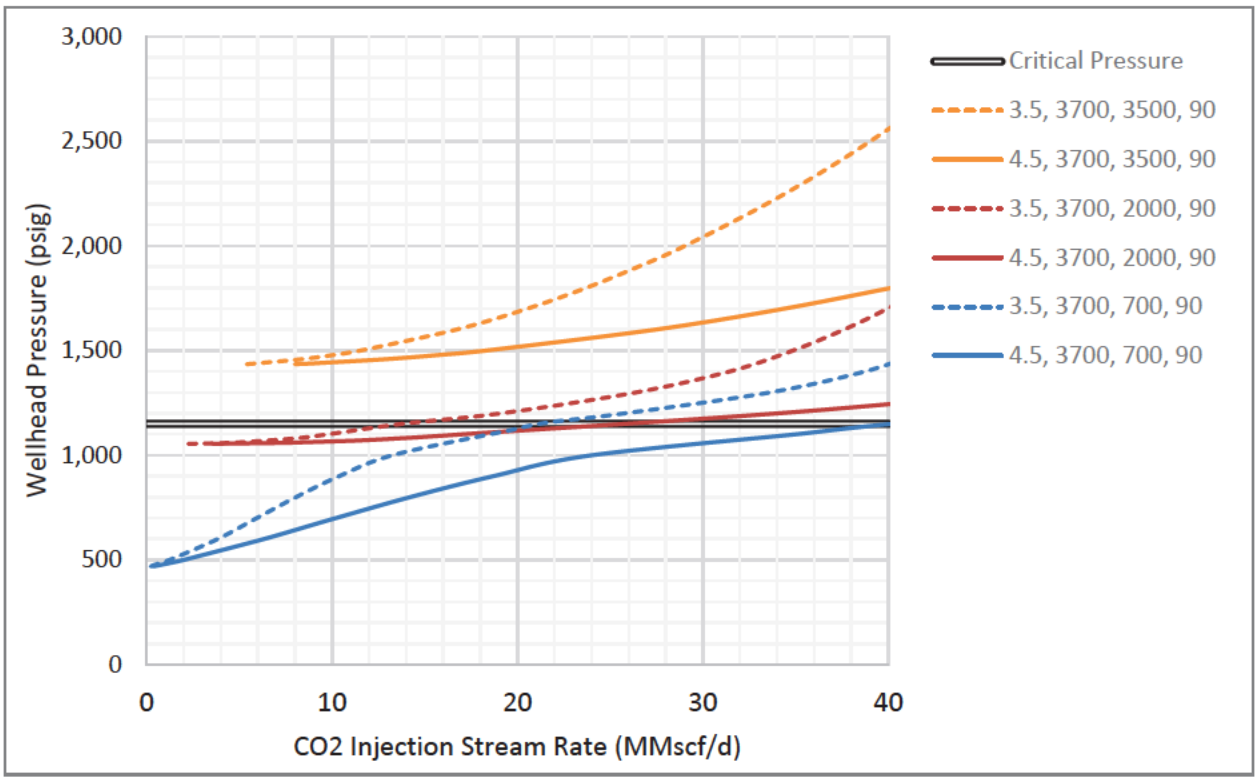

Figure 16: 64-35N CO_2 Injection: High Permeability Thickness and Tubing Sensitivity

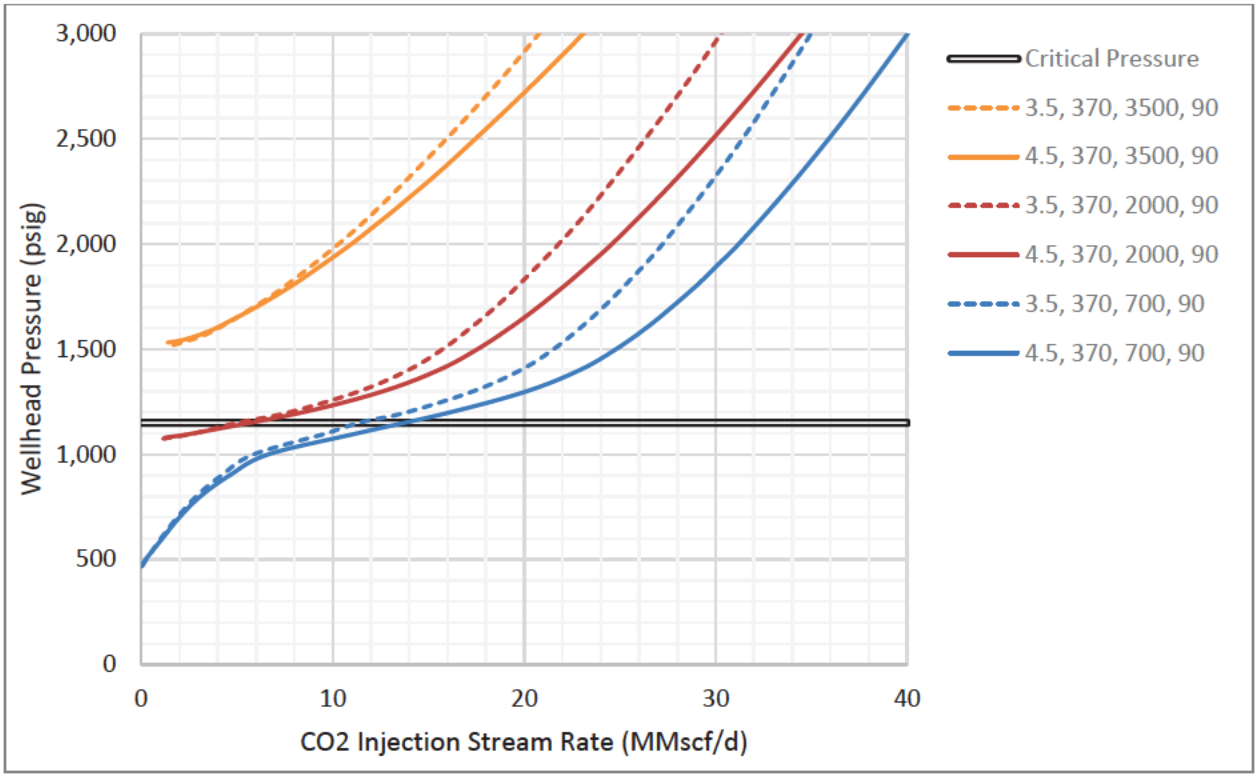

Figure 17: 64-35N CO_2 Injection: Low Permeability Thickness and Tubing Sensitivity

4.4 Well 64-27N Match and CO_2 Injectivity Study

This section first presents the 64-27N well match and secondly presents the injectivity study.

4.4.1 Well 64-27N Match

Table 14 lists three injection gradients from 1950 for well 64-27N. The reservoir pressure is from an Aera material balance model for the 64-zone (>300 Reference Documents>Reservoir Engineering>2021_09_29 Historical Gas Injection>2002 Material Balance>64zoneMatbal.xls).

Table 14: 64-27N: Measured Injection Gradients — 1950

Date	Measured Q (MMscf/D)	Measured BHP (psig)	Modeled BHP (psig)
	0.00		1,150
10/10/1950	8.895	1,641	
10/12/1950	6.286	1,463	
10/16/1950	7.208	1,612	

Figure 18 shows two equivalent matches for the measured injection gradients, and these are:

- kh = 740 mD.ft with skin = 0
- kh = 3,700 mD.ft with skin = 34

Single point measured injection gradients cannot determine kh and skin separately—that requires a pressure transient test. Petrophysical analysis of the well could also be useful. This study uses the skin = 0 solution. This is acceptable as the modeling is for the wellbore and the reservoir, essentially a resistance to injection. Details of flow in the reservoir are to be covered by Aera's reservoir simulation work.

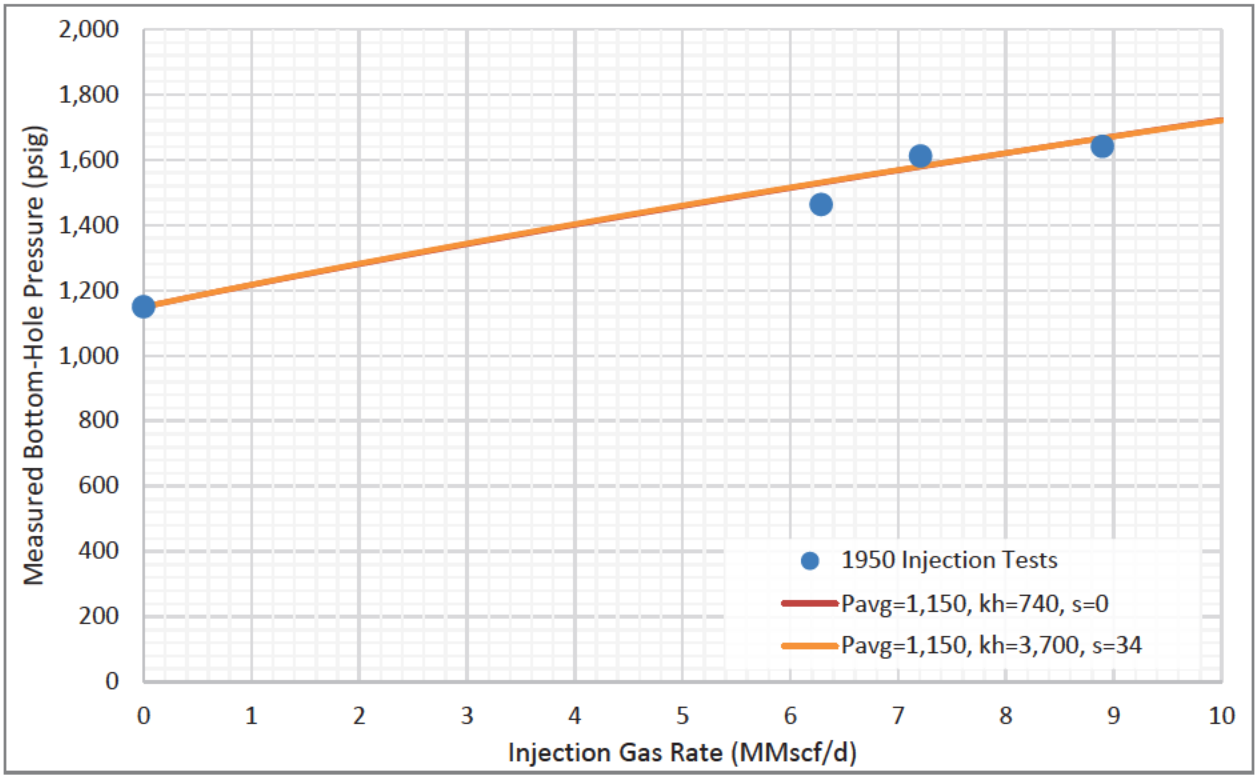

Figure 18: 64-27N: Matched Measured Injection Gradients—1950

4.4.2 Well 64-27N CO_2 Injectivity Study

This last measured data from the well was over 70 years ago, and that creates uncertainty for the injectivity for this well. Assume the well had no skin, and then the best estimate of permeability thickness is 740 mD.ft. If disposal water is around this well, relative permeability effects could drop the effective permeability to 1/10 (74 mD.ft).

Figure 19 and Figure 20 show the required well injection stream pressure versus injection stream rate for the permeability thicknesses. Conclusions are:

- 740 mD.ft is still best with 4 1/2 rather 3 1/2 in. tubing
- 74 mD.ft is best with 2 7/8 rather 3 1/2 in. tubing – if disposal water is in the zone around a well, it will negatively affect the injectivity of the well.

Reservoir simulation is important to understand if a well may be wet. If possible, it is recommended to perform a gradient survey to check if a well is wet prior to repurposing to a CO_2 injection stream well.

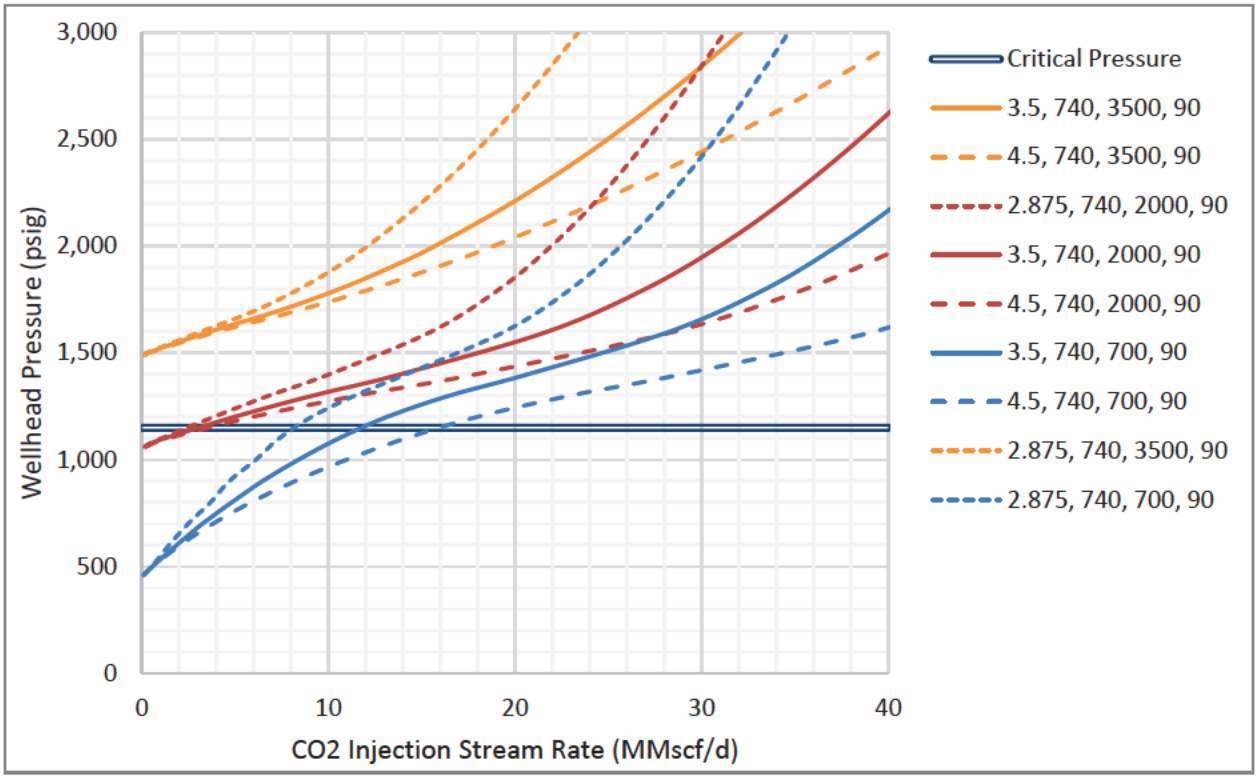

Figure 19: 64-27N CO_2 Injection: High Permeability Thickness and Tubing Sensitivity

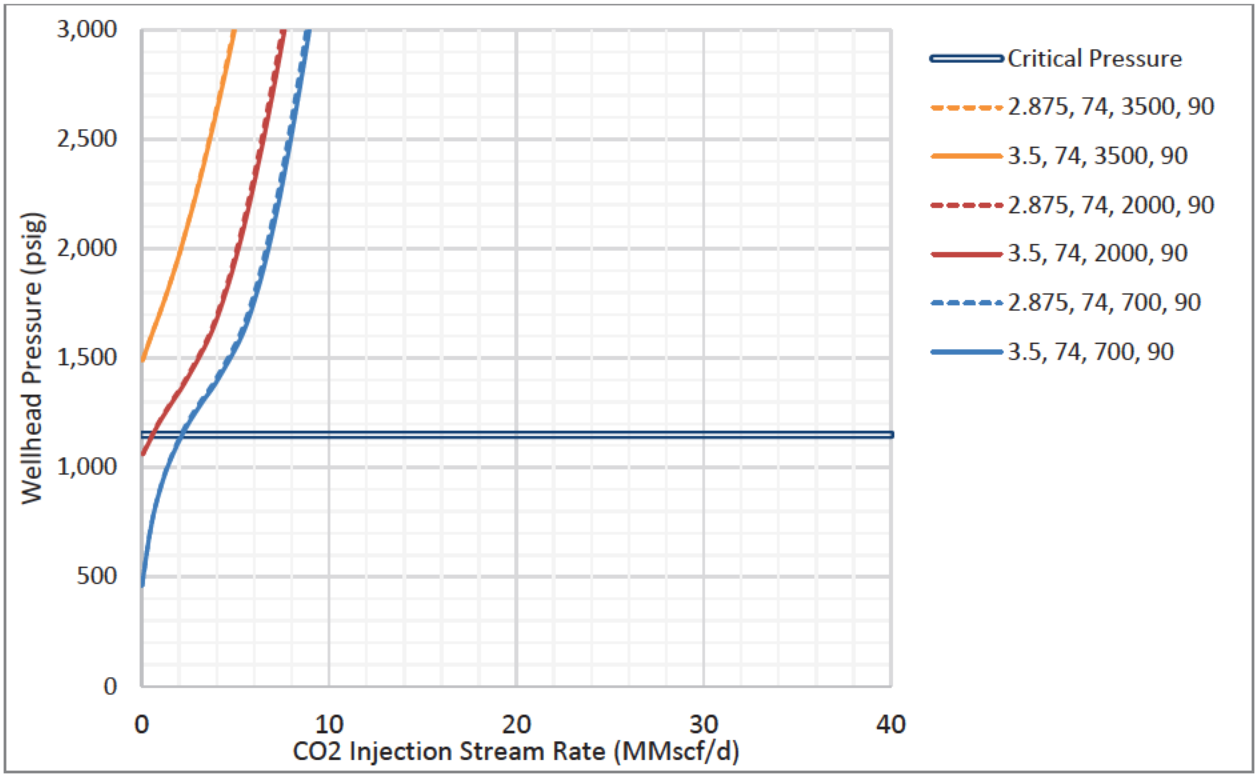

Figure 20: 64-27N CO_2 Injection: Low Permeability Thickness and Tubing Sensitivity

4.5 Well 49-35N Match and CO_2 Injectivity Study

This section first presents the well 49-35N match and secondly presents the injectivity study.

4.5.1 Well 49-35N Match

Table 15 lists measured injection points from 1981 for well 49-35N. The reservoir pressure is from an Aera material balance model for the 64-zone (>300 Reference Documents>Reservoir Engineering>2021_09_29 Historical Gas Injection>2002 Material Balance>64zoneMatbal.xls.

Table 15: 49-35N: Measured Injection Points — 1981

Date	Measured Q (MMscf/D)	Measured WHP (psig)	Modeled BHP (psig)
	0.00		1,255
Sep-1981	3.65	1,050	1,175
Oct-1981	3.40	1,050	1,185
Oct-1981	3.40	1,150	1,310
Dec-1981	5.10	1,220	1,330
Dec-1981	4.80	1,180	1,291
Dec-1981	3.35	1,180	1,350

Figure 21 shows the match from the 1981 test points applied to the shut-in and flowing test from 1981. The best estimate permeability thickness is 3,700 mD.ft, for a skin of 0. This is the same kh estimated for well 64-35N.

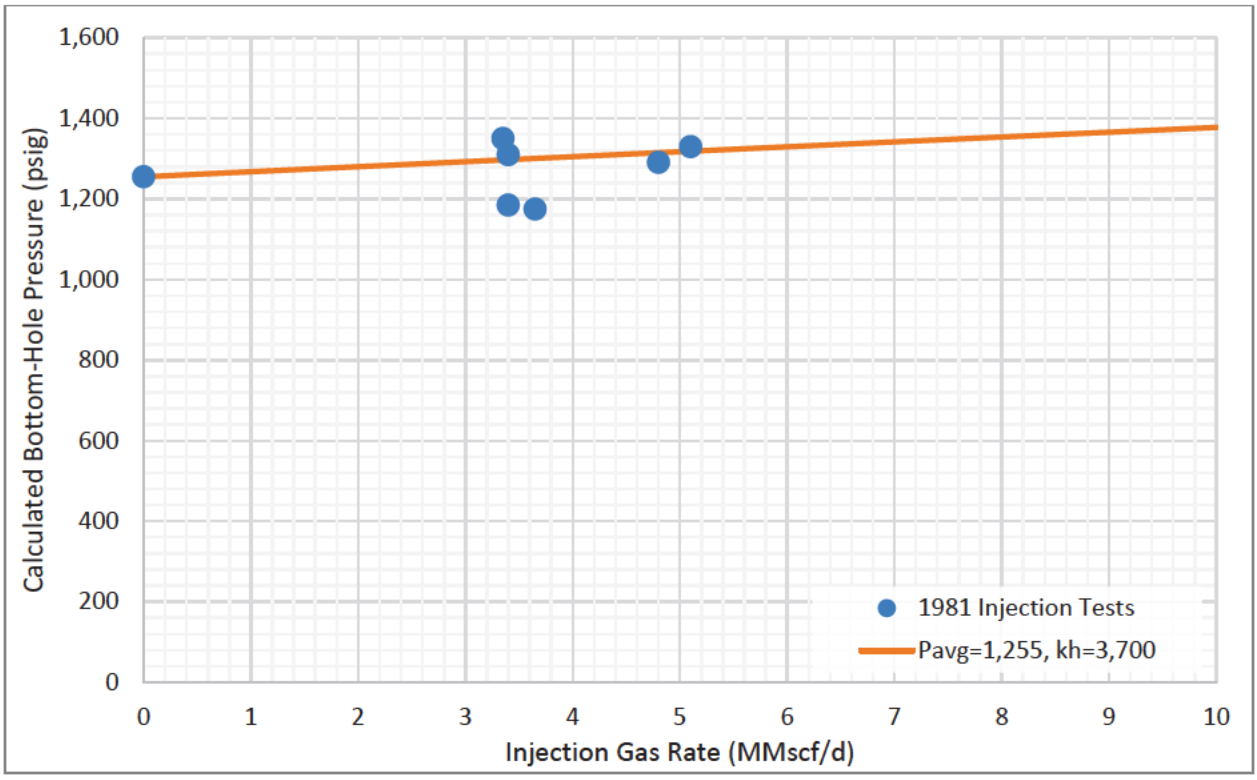

Figure 21: 64-35N: Matched Injection Points—1981

4.5.2 Well 49-35N CO_2 Injectivity Study

Well 49-35N has the same injectivity as 64-35N, hence the previous injectivity study holds for this well.

4.6 64-Zone Injection Test Design

Injection tests are recommended for the determination of a well's injection area permeability to CO_2, skin, and average pressure. The previous nodal modeling highlighted the uncertainty in the permeability to CO_2 using high and low permeability thickness cases. Nodal modeling cannot independently determine permeability thickness and skin. A three-rate step-rate test could investigate the layer properties and the completion skin. If possible, it is best to inject a CO_2 stream into the formation as planned for the injection wells.

Kappa Engineering's SAPHIR software was used for test design assuming pure CO_2. The source of the CO_2 for an injection test is to be determined. The reservoir pressure for this study is 700 psig. The steps for the test are:

- Use properties of well 64-35N—permeability thicknesses of 3,700 and 370 mD.ft.
- Injection rates of 10, 20, and 30 MMscf/D as these are likely injection rates for a storage well.
- Injection time the same for each rate. Total injection times considered were 9 and 24 hours.

Figure 22 show the injection pressure response for cases injecting 9 and 24 hours for the 370 mD.ft case. The total injection time of 9 hours yields a BHP max = 3,100 psig with injection at WHP = 1,200 psig and WHT = 90 °F. The total injection time of 24 hours yields a BHP max = 3,500 psig with injection at WHP = 1,300 psig and WHT = 90 °F.

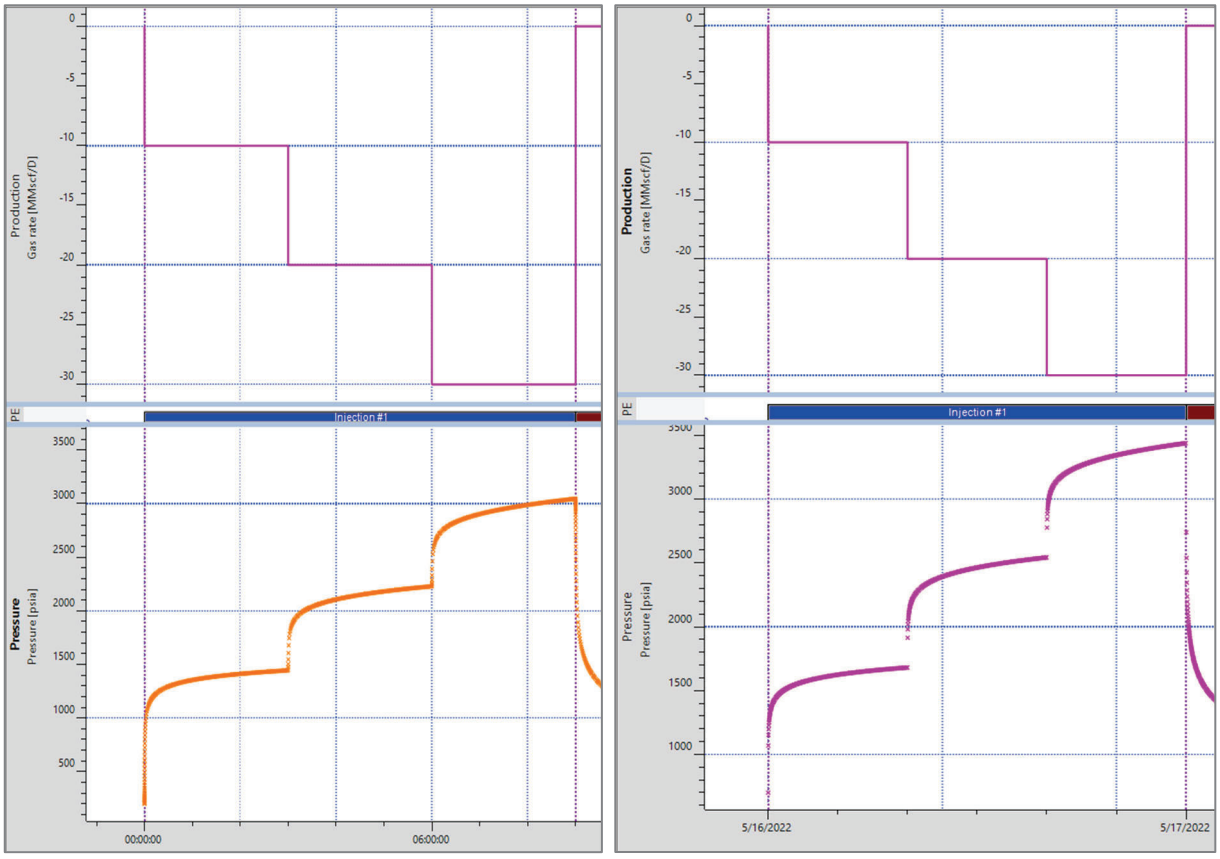

Figure 22: 64-Zone Injection Test: Injection Responses for 9 and 24 Hours

Figure 23 show the falloff pressure-derivative charts for 4 falloff tests. These falloffs exhibit layered responses with the lower permeability thickness exhibiting the greatest response. These falloffs show that it can take longer shut-in times compared to the injection time for conclusive layer differentiation.

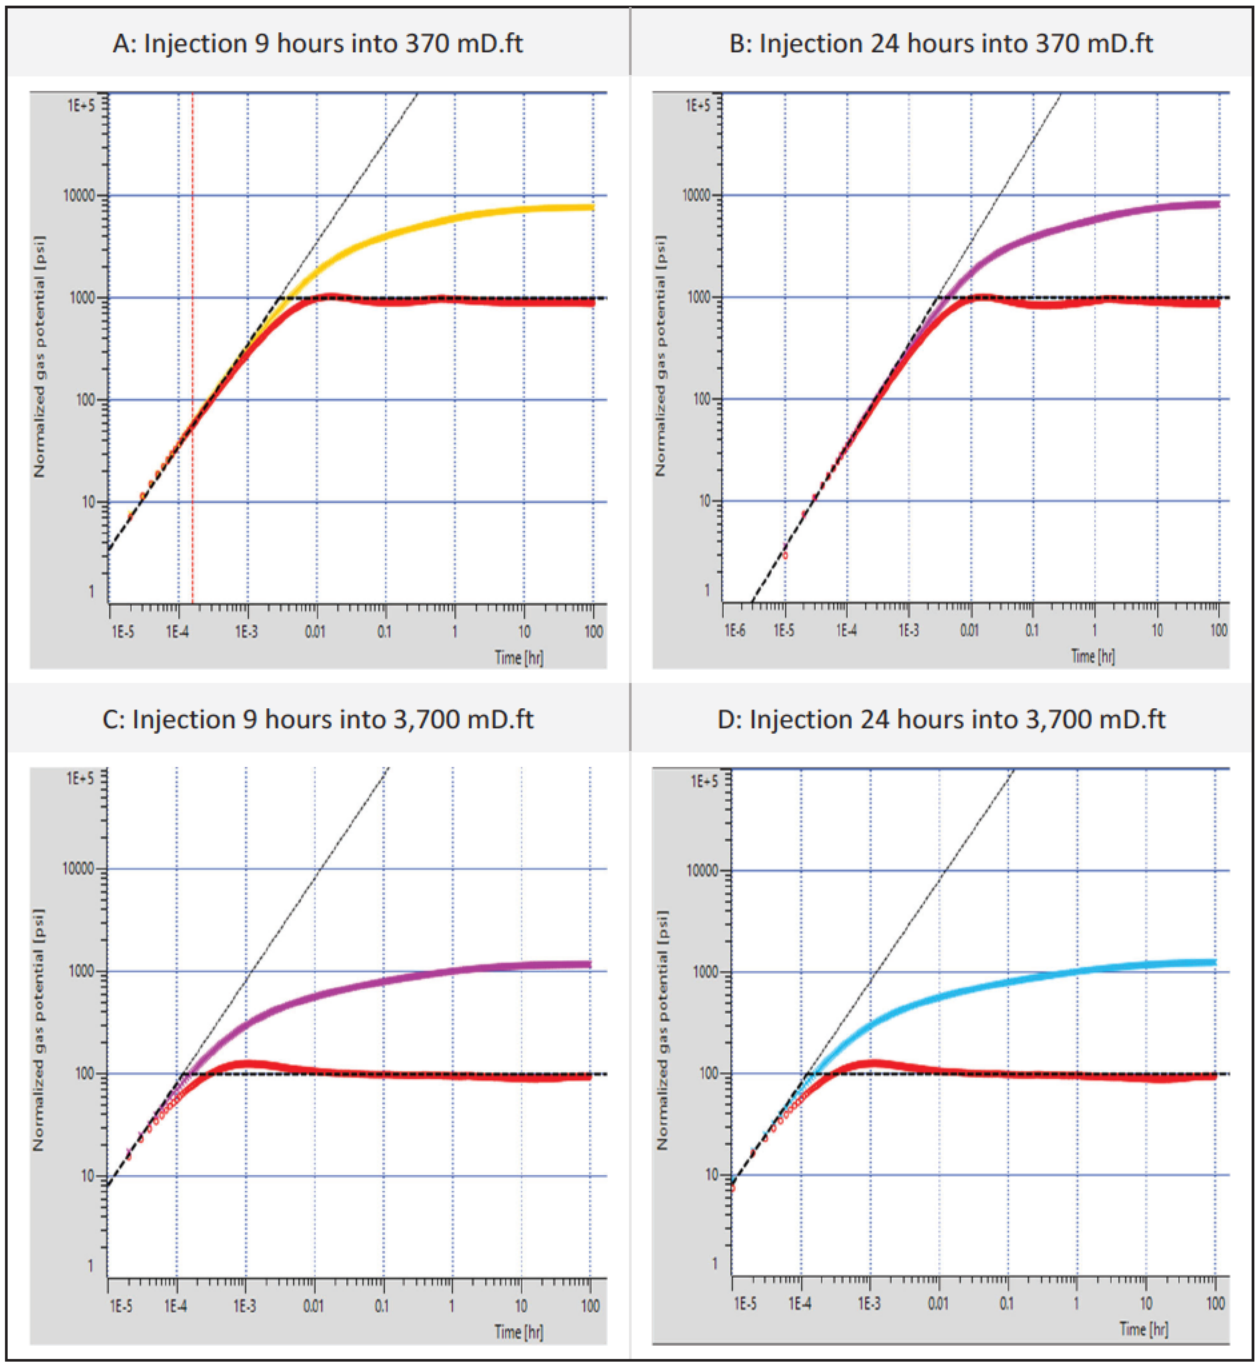

Figure 23: 64-Zone Injection Test: Injection Fall off Responses

Figure 24 shows the layer injection rates for Type 1, 2, 3, and 4 rocks assuming all layer types are at the same initial pressure for the 9 hour injections. In this figure, Type 1 is the green line, Type 2 is the dark blue line, Type 3 is the magenta line, and Type 4 is the blue line. The Type 1 rock takes most of the flow and Type 4 rock takes essentially no flow. There are wells where the Type 3 and Type 4 rocks were not produced, and hence their pressures are higher and their ability to take rate even less. Type 1 and Type 2 rocks will dominate the injectivity test analysis.

Figure 25 shows the layer cross flow rates for Type 1, 2, 3, and 4 rocks assuming all layer types are at the same initial pressure. The colors of the lines are the same as in Figure 24. Gas from the Type 1 rock layer flows out and into the Type 2, 3, and 4 rocks. Layer crossflow can obscure the falloff analysis, and it is best to stay shut-in until crossflow is minimal. In this case, that would be about 18 hours, or twice the time of the injection period.

For an injection time of X hours, the shut-in time should be 2X hours. Therefore:

- For an injection of 9 hours, the shut-in should be at least 18 hours.
- For an injection of 24 hours, the shut-in should be at least 48 hours.

The longer the test, the better the layered diagnosis.

Figure 26 and Figure 27 show the percentage of total flow to each layer for 9-hour and 24-hour injections. The time length of the injection steps doesn't affect the contribution per layer during a Pressure Transient Test (PTA). Injection change per layer is a long-term consideration not possible prior to converting the field to CO_2 sequestration. Note that the Type 4 rock does not take the injection fluid, and therefore those wells that did not produce this rock do not need to be redrilled to include that rock.

Figure 28 show the area of investigation for the same injection conditions of previous. Total injection time and permeability affects the radius of injection.

- The radius of investigation increases with the square root of time.
- The radius of investigation increases with the square root of permeability.

The cases yield the following radius of investigation:

- Permeability thickness = 370 mD.ft
  - For 9 hours of injection, radius = 116 ft.
  - For 24 hours of injection, radius = 253 ft.
- Permeability thickness = 3,700 mD.ft
  - For 9 hours of injection, radius = 318 ft.
  - For 24 hours of injection, radius = 446 ft.

Past production history gives reasonable certainty re the best test design. There is not a requirement for excessive injection times. The recommended range of tests are:

- Minimum recommendation is a 9 hour three-step test with each step of 3 hours at rates of 10, 20, 30 MMscf/D, followed by a 15 hour shut-in
- Maximum recommendation is a 24 hour three-step test with each step of 8 hours at rates of 10, 20, 30 MMscf/D, followed by a 24 hour shut-in

4.7 64-Zone Injection Sensitivity for Reservoir Modeling

To assist with the reservoir simulation modeling, Aera's reservoir modelers requested well injection sensitivity charts for the following combinations:

- Average area injection pressure = 400, 2,800, and 4,200 psig
- Permeability thickness = 1,000 and 3,000 mD.ft
- Skin = –5, 0, and 5
- The well model is per Blade's average well design recommendation documented separately

This section presents the injection sensitivity charts.

Figure 29 and Figure 30 show the required well injection stream pressure versus injection stream rate for the different injection temperature and average pressures for cases of 1,000 and 3,000 mD.ft respectively. The data for these charts was provided to Aera in a Microsoft Excel workbook.

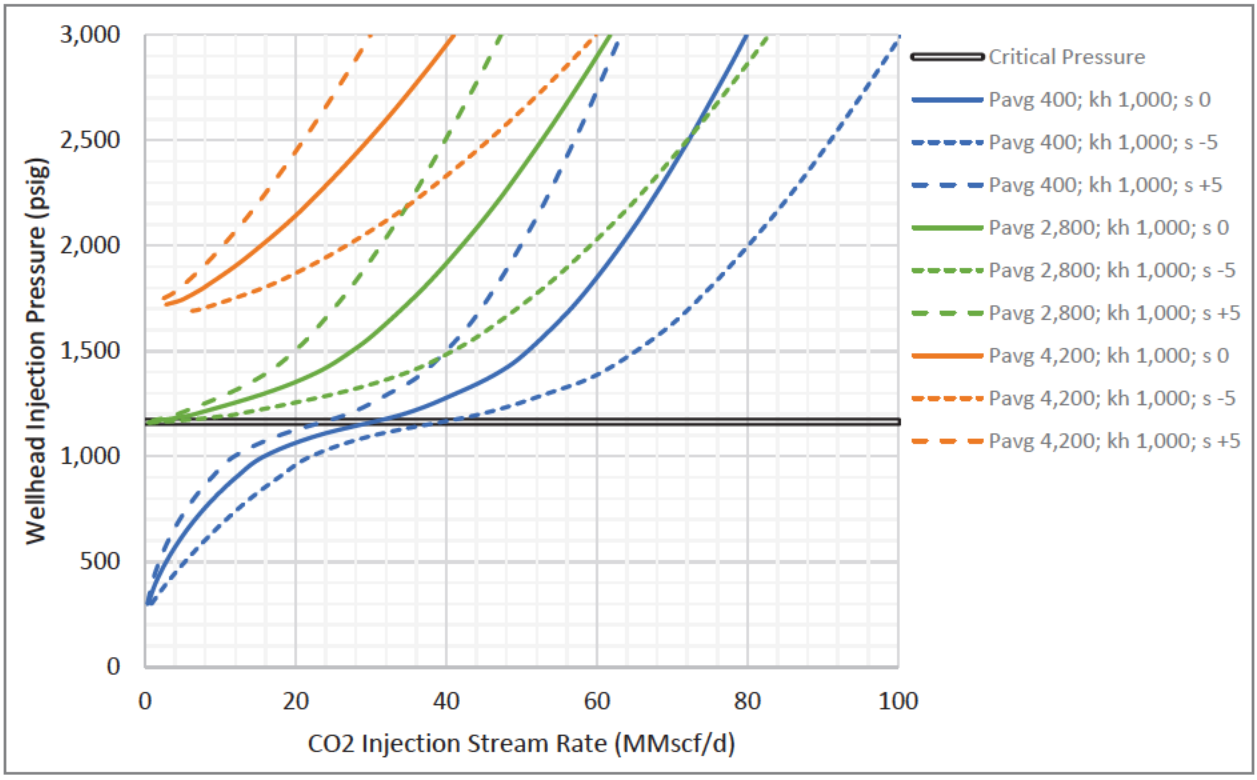

Figure 29: 64-Zone Injection Sensitivity: 1,000 mD.ft

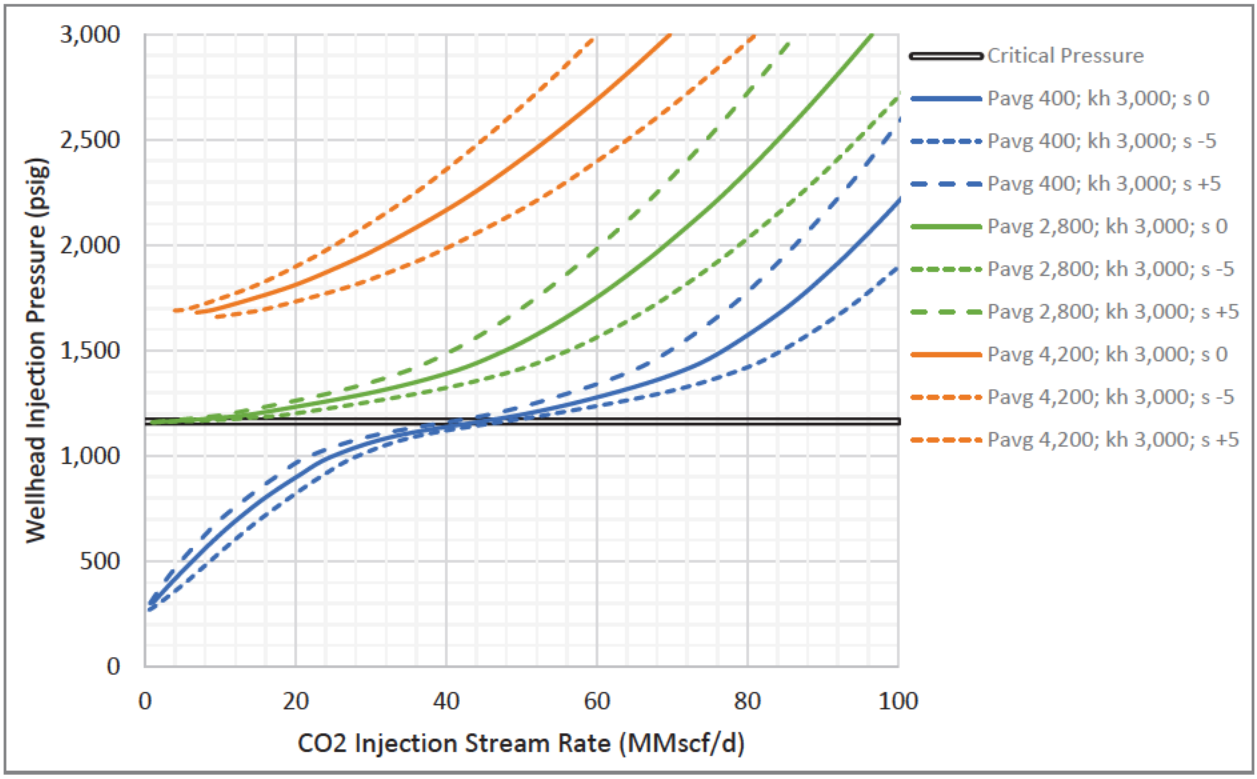

Figure 30: 64-Zone Injection Sensitivity: 3,000 mD.ft

4.8 Temperature and Pressure Update for 64-25N

In November 2023, Aera updated the maximum wellhead injection temperature to 180°F and the maximum injection bottomhole pressure to 80% of the fracture gradient. For well 64-35N, the maximum reservoir pressure at the mid-point of the injection zone (average reservoir pressure of injection plume) is then 4,470 psig. Previously, the maximum temperature was 110 °F and the maximum pressure was 4,200 psig. The increase in temperature and pressure means that the well design needed to be checked, and Table 16 shows the required profiles. The injection is the same CO2 stream presented earlier.

Table 16: 64-25 Updated Well Gradient Conditions

	WHT (°F)	WHP (psig)	Q (MMscf/d)	P,avg (psig)	kh (mD.m)
Final Injection	180	2,784	20	4,470	3,700
Initial Injection	180	1,060	20	700	3,700
Final Shut in	80	2,290	0	4,470	3,700
Shut in (if CH4 charged)	80	3,943	0	4,470	3,700
Final Blowout	-70	0	73	4,470	3,700
Blowout (if CH4 charged)	118	0	74	4,470	3,700

Figure 31 and Figure 32 show the updated pressure and temperature gradients respectively for CO2 stream.

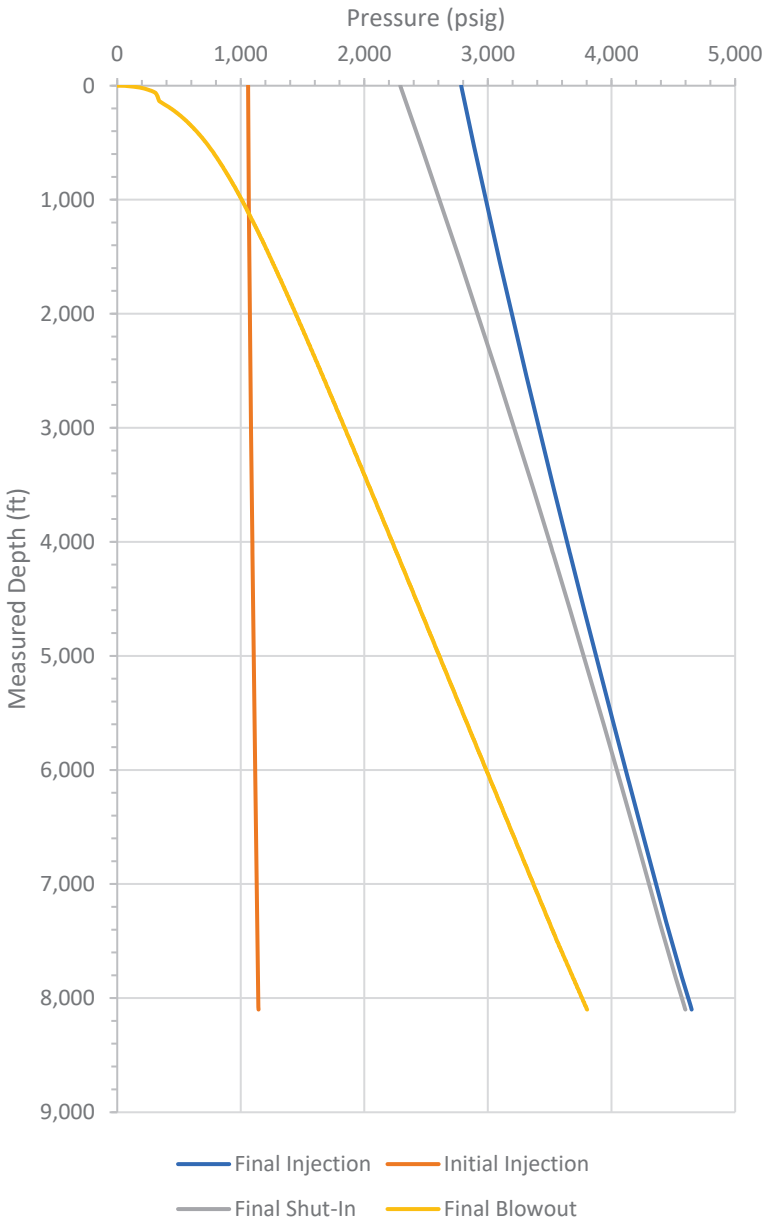

Figure 31: 64-25 Updated Pressure Gradients for CO2 Injection Stream

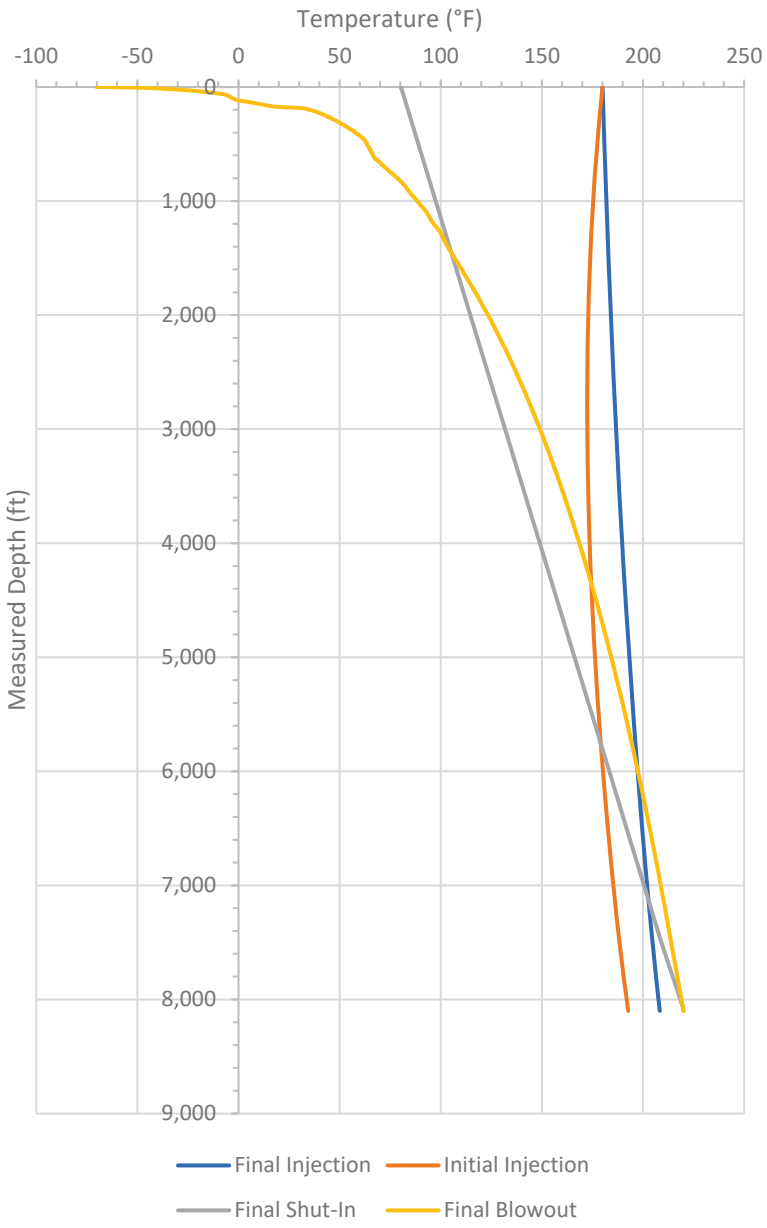

Figure 32: 64-25 Updated Temperature Gradients for CO2 Injection Stream

5 Materials Selection

5.1 Background

Literature indicates that corrosion in dense phase CO_2 is almost negligible if the water content in the injectate is below the water solubility limit. However, corrosion poses a threat when the water condenses and forms a separate liquid (aqueous) phase. Corrosion resistance in carbon capture and storage (CCS) wells is one of the key factors that determines the appropriate material for casing, tubing, and liners in CCS applications.

Aera indicated that there are two injection streams considered in their CCS project. Table 17 shows the proposed CO_2 injection stream components and composition concentrations [3] considered in this study. Aera also indicated that CO_2 injection starts with the pre-combustion stream only and is then mixed with post combustion stream afterwards. The target injection rates are as follows:

- End of 1st Quarter 2026: Pre-combustion stream at 10 MMscf/D
- May 1st 2026: Pre combustion stream at 10 MMscf/D + Post combustion stream at 23 MMscf/D
- May 1st 2027: Pre combustion stream at 10 MMscf/D + Post combustion stream at 70 MMscf/D

Table 17: CO_2 Injection Stream Composition

Component	Pre-Combustion	Post-Combustion
CO_2	95 – 99.9%	98 – 99.9%
CH_4	0.05 – 2.0%	0%
C_2	0.02 – 1.0%	0%
C_3	0.03 – 1.0%	0%
C_4	0.02 – 1.0%	0%
C_5+	0.01 – 0.5%	0%
Lube Oils	5 – 10 ppm (m)	5 – 10 ppm (m)
N_2	0 – 0.05%	0 – 0.05%
O_2	<50 ppm (v)	<50 ppm (v)
CO	0	<100 ppm (v)
NO_x	0	<150 ppm (v)
SO_2	0	<10 ppm (v)
NH_3	0 – 10 ppm (v)	0 – 10 ppm (v)
H_2S	2 – 10 ppm (v)	0
Sulfur	3 – 30 ppm (v)	0
Ar	0	0 – 10 ppm (v)
H_2O	<258 ppm (m)	<258 ppm (m)

Blade undertook the following steps to assess the materials for the casing, tubing, and liners:

- Evaluate the water solubility in pre-combustion, and post-combustion injectates

- Identify the materials that can demonstrate resistance in wet CO_2
- Identify the materials that can demonstrate resistance in mixed reservoir fluid – CO_2 conditions

The water solubility and corrosion rates were determined using a thermodynamic modeling software called OLI v. 11. Corrosion resistance of carbon steel, 13Cr, modified 13Cr, modified 17 Cr and 22Cr in the environment that develops in the CCS well was studied.

5.2 H_2O Solubility in Super Critical CO_2

The solubility limit of water in super critical CO_2 dictates the maximum amount of water that can be held in the super critical CO_2 phase without condensing a separate liquid (aqueous) phase. Once the water in the system exceeds the water solubility limit at a particular temperature and pressure, a separate liquid water (aqueous) phase saturated with CO_2 forms. This separate liquid water (aqueous) phase due to its high acidity (low pH) is very corrosive to carbon steels and stainless steels.

Figure 33 shows the water solubility limit in dense phase CO_2 for pre-combustion and post-combustion streams at the injection temperature of 94°F, and at varying pressures of 0 to 5,000 psig. The figure shows that the composition of the injection stream affects the amount of water that can be held in the dense phase CO_2. At injection pressure of ~2,000 psig, the post-combustion injection stream can hold more water in the condensed phase (0.45 mol%) than in the pre-combustion injection stream (0.40 mol%). The figure also shows that the pre-combustion and post-combustion injection stream can hold at least 0.18 mol% H_2O at ~1,000 psi. This is the least amount of water that the pre-combustion stream and the post-combustion stream can hold at the injection temperature of 94°F. This implies that with the amount of H_2O in the pre-combustion and post-combustion injection streams, the water will remain in the dense phase CO_2 during injection.

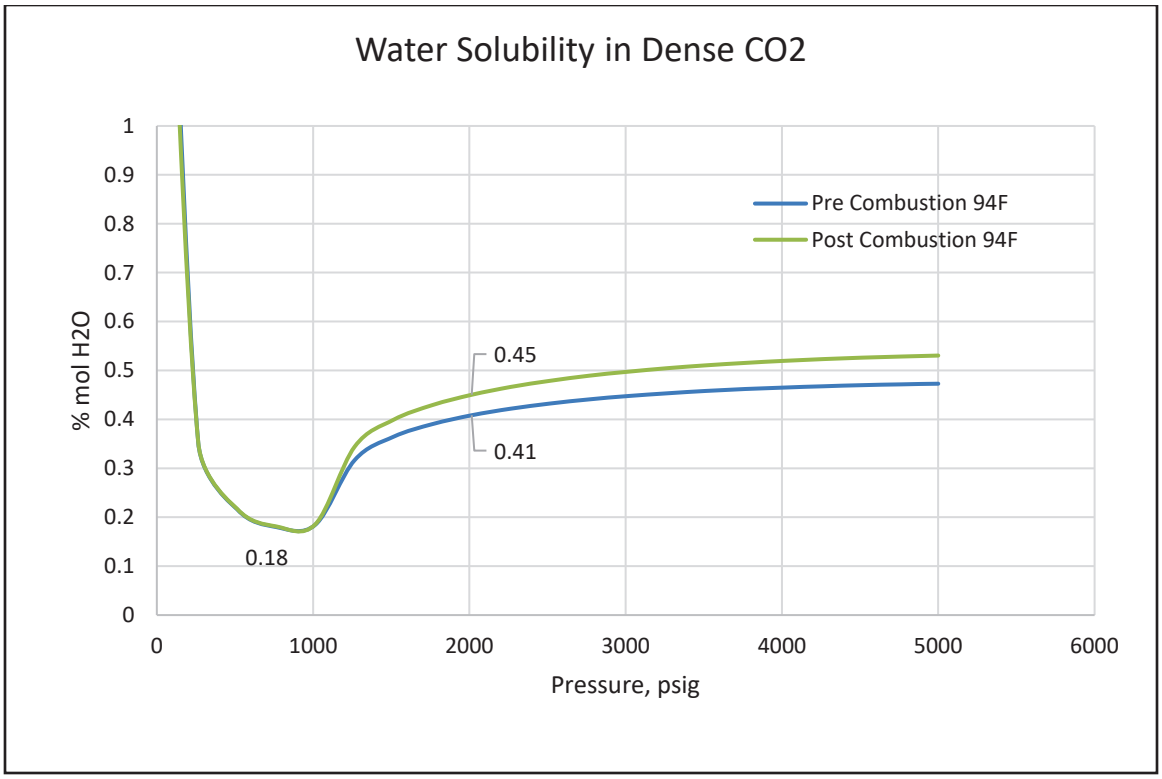

Figure 33: Water Solubility in Dense Phase CO_2 at Injection Temperature of 94°F

The temperature inside the well varies and may reach 241°F at the bottom of the well. Figure 34 shows the water solubility in dense phase pure CO_2, in the pre-combustion injection stream, and the post combustion injection stream at temperatures 94°F and 241°F. The figure shows that as the temperature increases, the water solubility in dense phase CO_2 also increases. This implies that the injectate will remain dry inside the well during injection if the water content in the injection stream is maintained at the level indicated in the proposed injection stream composition (Table 17). There should be no corrosion since the water in the dense phase CO_2 is way below the solubility limit.

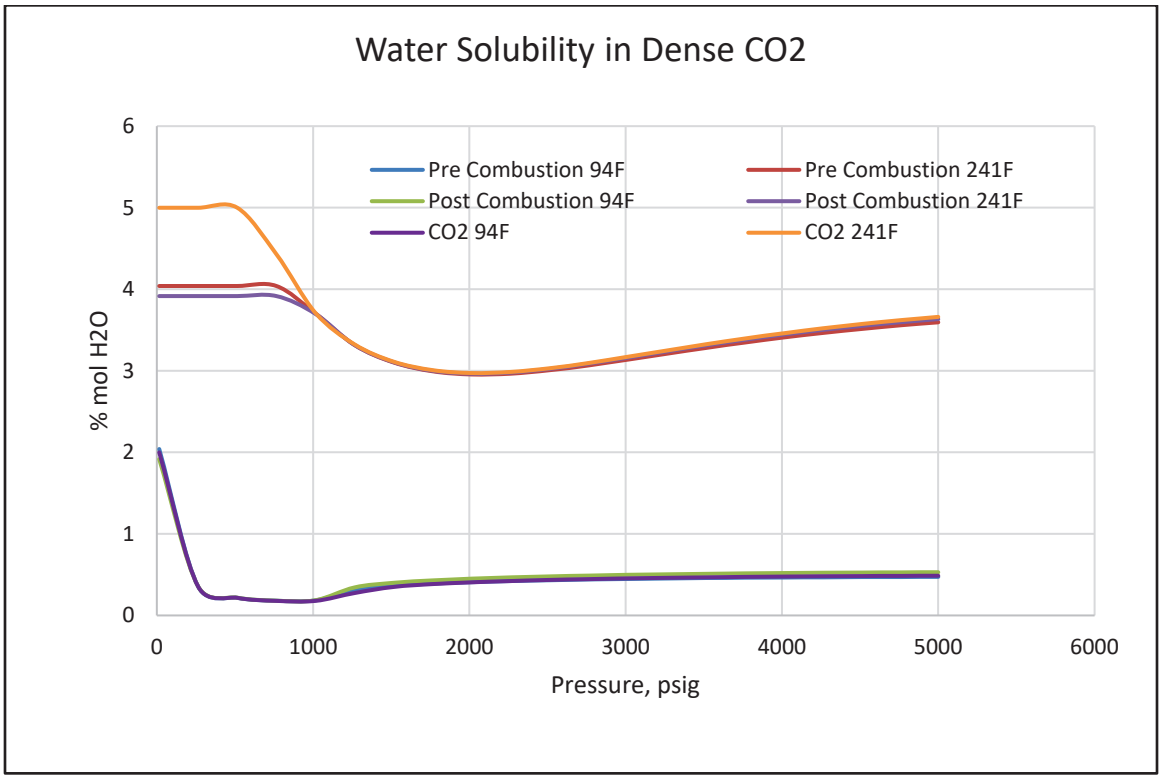

Figure 34: Water Solubility in Dense Phase CO_2 at Different Temperatures

Literature confirms that corrosion of carbon steel in super critical CO_2 containing 500 to 1,000 ppm H_2O is negligible [4] [5] [6]. This indicates that for the conditions that corrosion tests were carried out, the H_2O has not condensed out of the dense CO_2 fluid, and that the highly corrosive aqueous phase with super saturated CO_2 has not formed, i.e., no separate water phase has formed. For this same reason, the existing carbon steel pipelines used in CCS projects can transport super critical CO_2 without having corrosion issues.

5.3 Corrosion Evaluation

A corrosive aqueous phase with super saturated CO_2 may form in extreme cases and upset conditions when water in the injection stream exceeds the solubility limit at given temperature and pressure inside the well. This study estimates the corrosion rate during upset conditions when corrosive aqueous phase forms during injection and during shut in. The following materials were investigated:

- Carbon steel
- 13Cr
- Modified 13Cr
- Modified 17Cr
- 22Cr

The compositions of these materials considered in the thermodynamic model are reported in Section 9 Appendix A—Materials .

5.3.1 General Approach

Since the injected CO_2 will remain dry during injection period, there will be no separate liquid water (aqueous) phase that may lead to corrosion. However, there might be instances when upset conditions occur where H_2O in the injectate exceeds the maximum solubility indicated in Figure 33, and the liquid water (aqueous) phase precipitates from dense phase CO_2. Blade modeled the corrosion of candidate materials in the upset conditions during injection and during shut in. The following upset conditions were assumed:

- Excess water in the injection stream resulting in a separate liquid water (aqueous) phase
- Reservoir flow back into the well causing mixing of the injection stream with reservoir fluid

Thermodynamic models were built using the OLI MSE-SRK framework to establish the injectate and liquid phase compositions and the corrosion rates were estimated using the OLI Aqueous framework. The corrosion rates for candidate materials were determined based on thermodynamic prediction of the stability of metals, metal ions, oxides as function of temperature, pressure, and solution composition [7].

Figure 35 shows an example of injection time curve projected for Aera CCS well. Blade used the injection time curves for PROSPER analysis. Table 18 lists the conditions assumed in generating the temperature and pressure profiles. These profiles generated from PROSPER analysis were then used as inputs to the thermodynamic models. Table 74 and Table 75 in Section 9 Appendix A—Materials Additional Information, show the temperature and pressure values used in the OLI thermodynamic models.

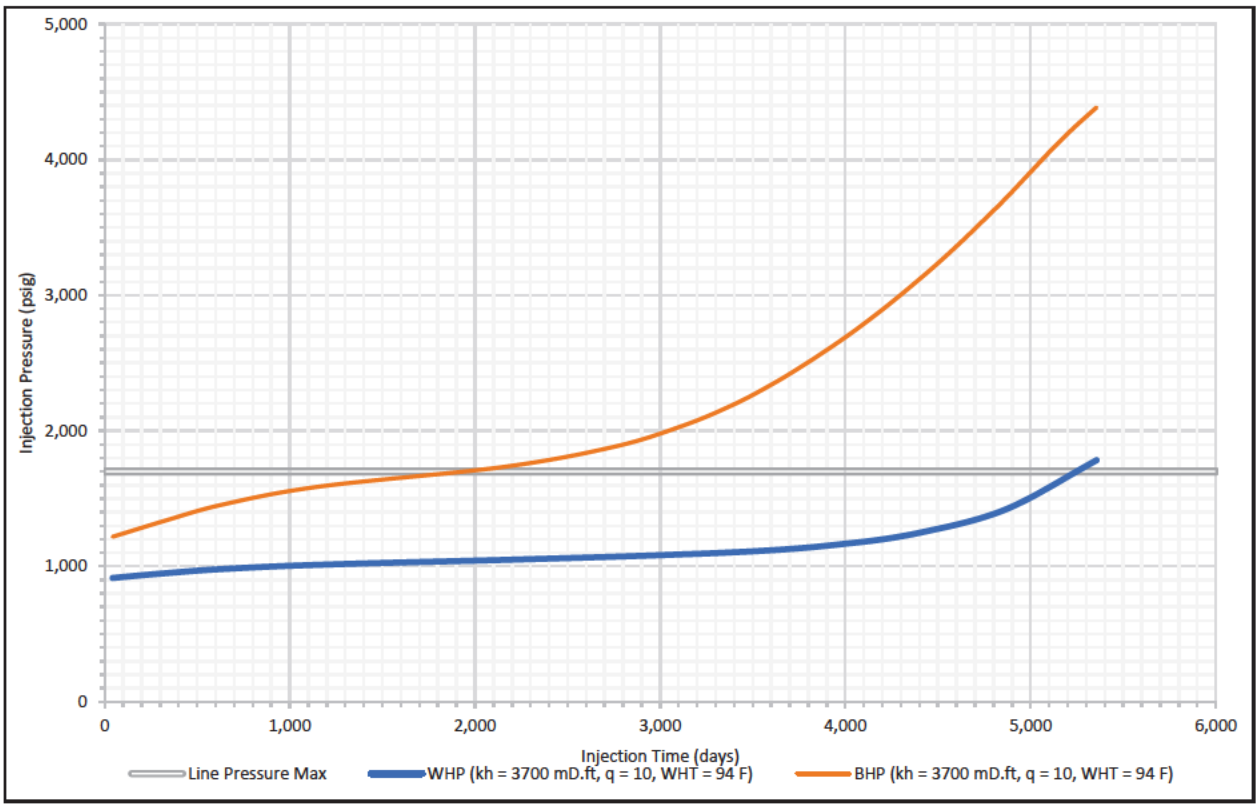

Figure 35: Injection Time Curve

Table 18: Temperature and Pressure Profile Codes

T/P Profile Code	Pavg	Q	kh	BHP
	psig	MMscf/d	md.ft	psig
KLo-10-1	400	10	740	1,552
KLo-20-1	400	20	740	2,220
KHi-20-1	400	20	3,700	1,046
KHi-20-2	1,500	20	3,700	1,783
KHi-20-3	2,600	20	3,700	2,800
KHi-20-4	3,700	20	3,700	3,887
KHi-20-5	4,200	20	3,700	4,387
Shut-in	3,700	0	N/A	4,200

5.3.2 Corrosion During Injection Alone

The water solubility curves in Figure 33 indicate that the pre injection and post injection streams will be dry i.e., no liquid water (aqueous) phase will form at the injection temperature of 94°F and estimated initial injection pressure of 2,000 psig. However, as previously discussed, upset conditions where excess water in the injectate may cause formation of a separate liquid water (aqueous) phase. In order to model the upset condition and determine the corrosion rate, the injection stream composition indicated in Table 19 were used in the thermodynamic model to establish the electrolyte chemistry. H_2O in the injectate was assumed to be equal to 4 mol% in order to form a separate liquid water (aqueous) phase.

Table 19: Injection Stream Composition Used in Thermodynamic Models

Component	Pre-Combustion	Post-Combustion
CO_2	95%	96%
CH_4	0.5 %	0%
C_2	0.1%	0%
C_3	0.1%	0%
C_4	0.1%	0%
C_5+	0.1%	0%
N_2	0.05%	0 – 0.05%
O_2	50 ppm (v)	50 ppm (v)
CO	0	100 ppm (v)
NO_x	0	150 ppm (v)
SO_2	0	10 ppm (v)
NH_3	0-10 ppm (v)	0 – 10 ppm (v)
H_2S	10 ppm (v)	0
Sulfur	30 ppm (v)	0
Ar	0	10 ppm (v)
H_2O	4%	4%

A separate analysis showed that the amount of NH_3 in the injection stream affects the pH and the corrosion rate of carbon steel, and 13Cr, but it has no effect on the corrosion rate of modified 13Cr, modified 17Cr, and 22Cr. The pH and corrosion rate comparison are included in the Section 9 Appendix A—Materials Additional Information. 0 ppm NH_3 in the injection stream lowers the pH and increases the corrosion rate of carbon steel and 13Cr. To be more conservative in the corrosion analysis, it was assumed that the injection streams have no NH_3 (0 ppm NH_3). In addition to the effects of NH_3 in the injection stream, the thermodynamic model also considers the effect of elemental sulfur with a particle size of 0.1 mm.

10 MMscf/D Pre-combustion Injection

The injection starts with the pre-combustion stream at injection rate of 10 MMscf/D. The facilities function in OLI was used to equilibrate the composition of the pre-combustion injection stream at different temperature and pressure conditions. The resulting liquid water phase chemistry was used to determine the pH and corrosion rates of carbon steel, 13Cr, modified 13Cr, modified 17Cr and 22 Cr at different temperature and pressure conditions. Figure 36 shows the estimated pH of the resulting liquid phase forming from the pre-combustion stream at different temperature and pressure conditions during injection and during shut-in conditions. Results show that pH ranges from 3.0 to 3.2 and the lowest pH occurs during shut-in conditions.

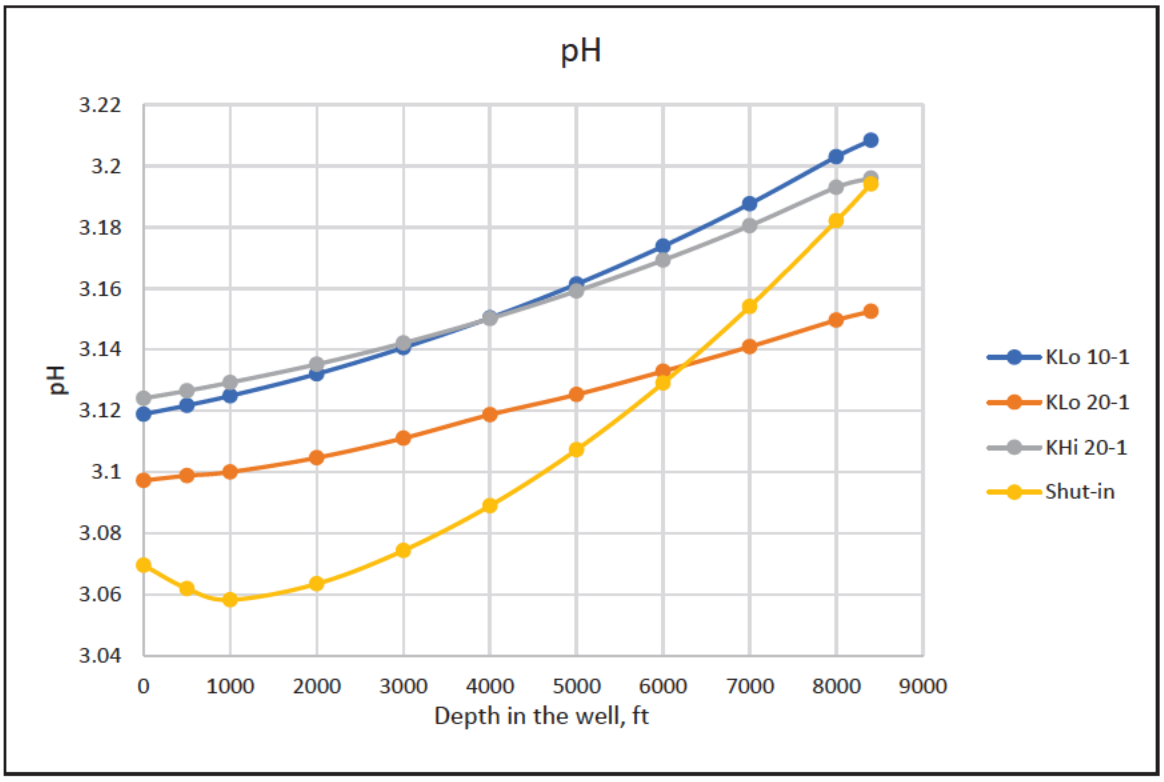

Figure 36: pH of Aqueous Phase from Pre-Combustion Injectate

Figure 37 shows the estimated corrosion rate of carbon steel in the aqueous phase forming from the dense phase pre-combustion stream. The corrosion rate of carbon steel is extremely high, greater than 500 mpy for injection and shut-in conditions. This implies that any upset condition in the system is extremely corrosive for carbon steel. Therefore, carbon steel is not suitable for casing, tubing, liners and exposed equipment in CCS wells.

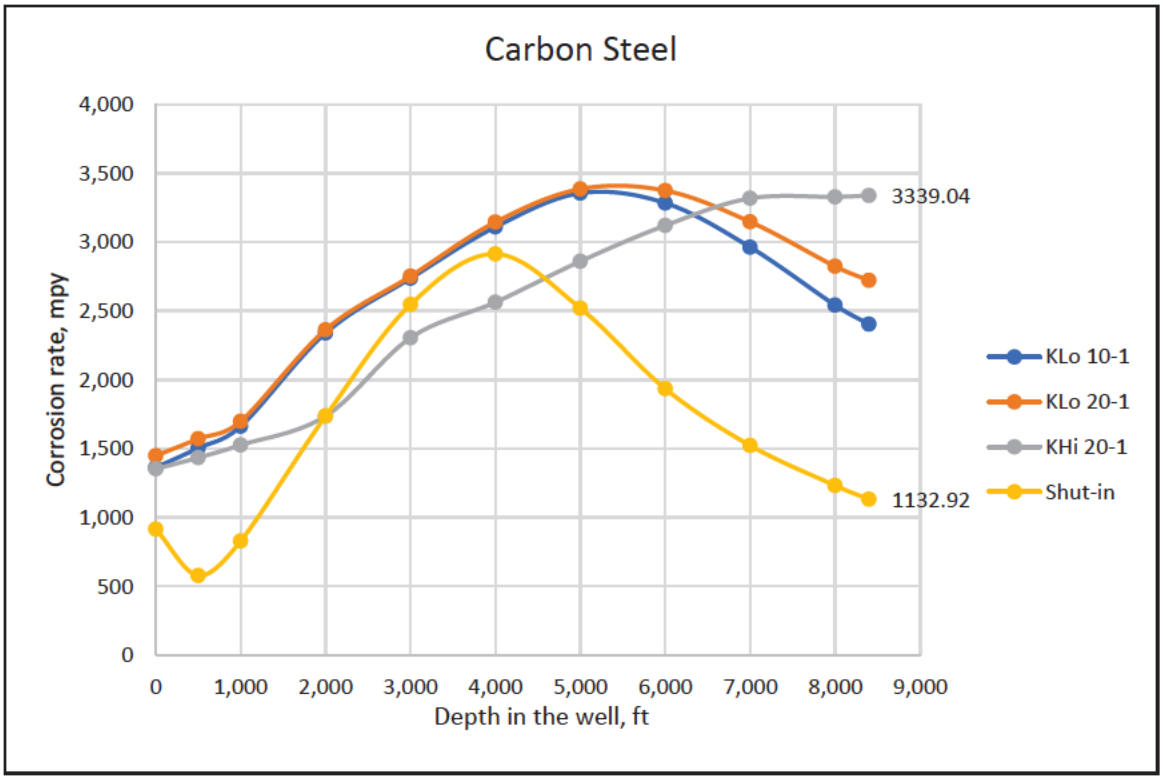

Figure 37: Corrosion of Carbon Steel in the Aqueous Phase from Pre-Combustion Injectate

Figure 38 shows the corrosion rate for 13Cr in the liquid (aqueous) phase formed from the pre-combustion stream at the start of injection and during shut-in. The corrosion rate of 13Cr reaches 24 mpy based on the Klo-10-1 temperature and pressure conditions during injection. The maximum corrosion rate estimated for 13Cr during shut-in is up to 99 mpy. Due to high corrosion rate of 13Cr during injection and shut-in, it is not suitable material for tubing and liner applications.

Figure 39 shows the corrosion rate for modified 13Cr in the liquid (aqueous) phase from the pre-combustion stream at the start of injection and during shut-in. The corrosion rate of modified 13Cr is lower than the corrosion rate of carbon steel and 13Cr, with the maximum corrosion rate of 3.93 during shut in. The estimated corrosion rate for modified 13Cr during injection is ~1.34 mpy at the bottom of the well.

The corrosion rate of modified 17Cr and 22 Cr are shown in Figure 40 and Figure 41, respectively. The corrosion rate of 17Cr is slightly lower than modified 13Cr, with 2.18 mpy corrosion rate in the shut-in condition and 0.74 mpy corrosion rate during injection. The results of the analysis indicate that 22Cr has the highest corrosion resistance among the materials analyzed. The maximum corrosion rate of 22Cr is less than 1 mpy in both injection and shut-in conditions.

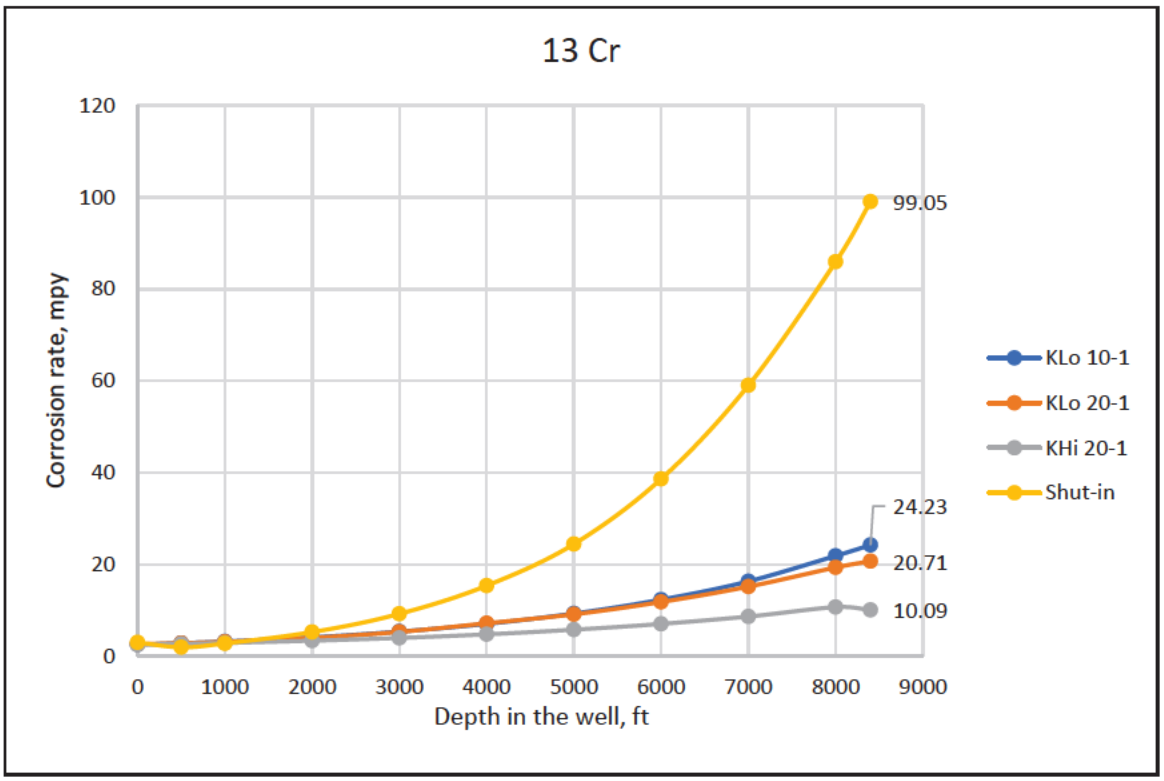

Figure 38: Corrosion of 13 Cr in the Aqueous Phase from Pre-Combustion Injectate

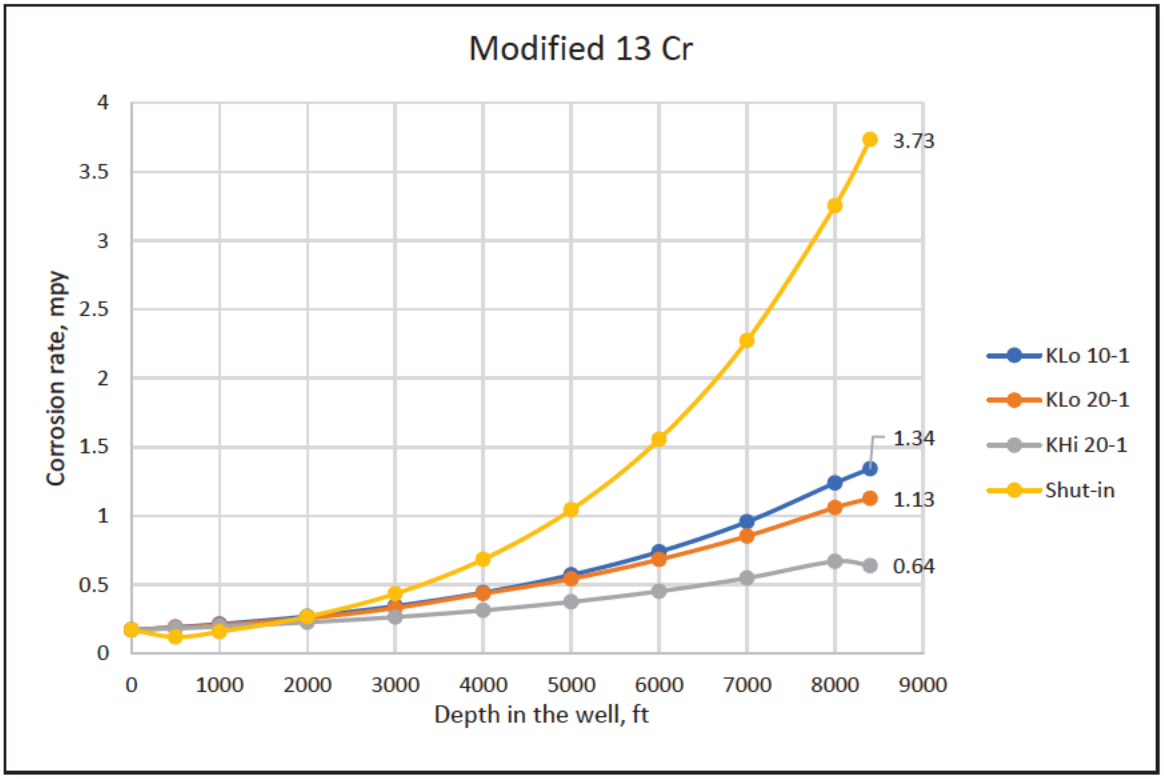

Figure 39: Corrosion of Modified 13 Cr in the Aqueous Phase from Pre-Combustion Injectate

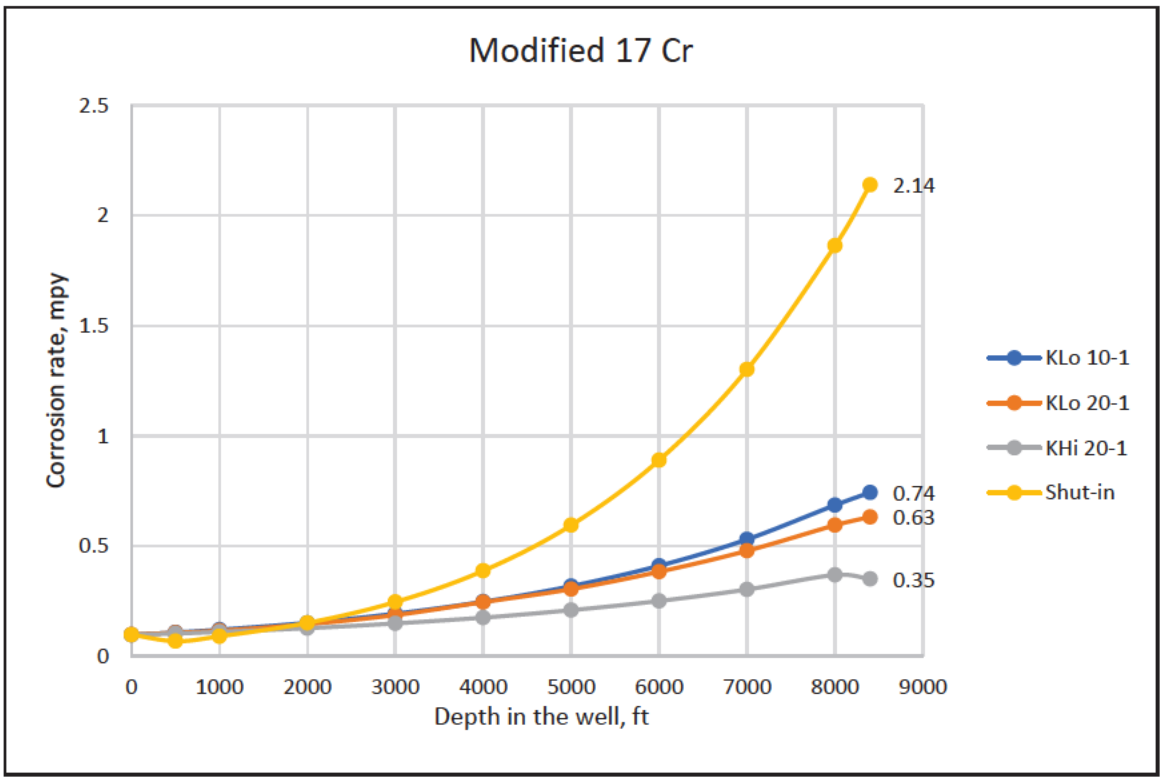

Figure 40: Corrosion of Modified 17 Cr in the Aqueous Phase from Pre-Combustion Injectate

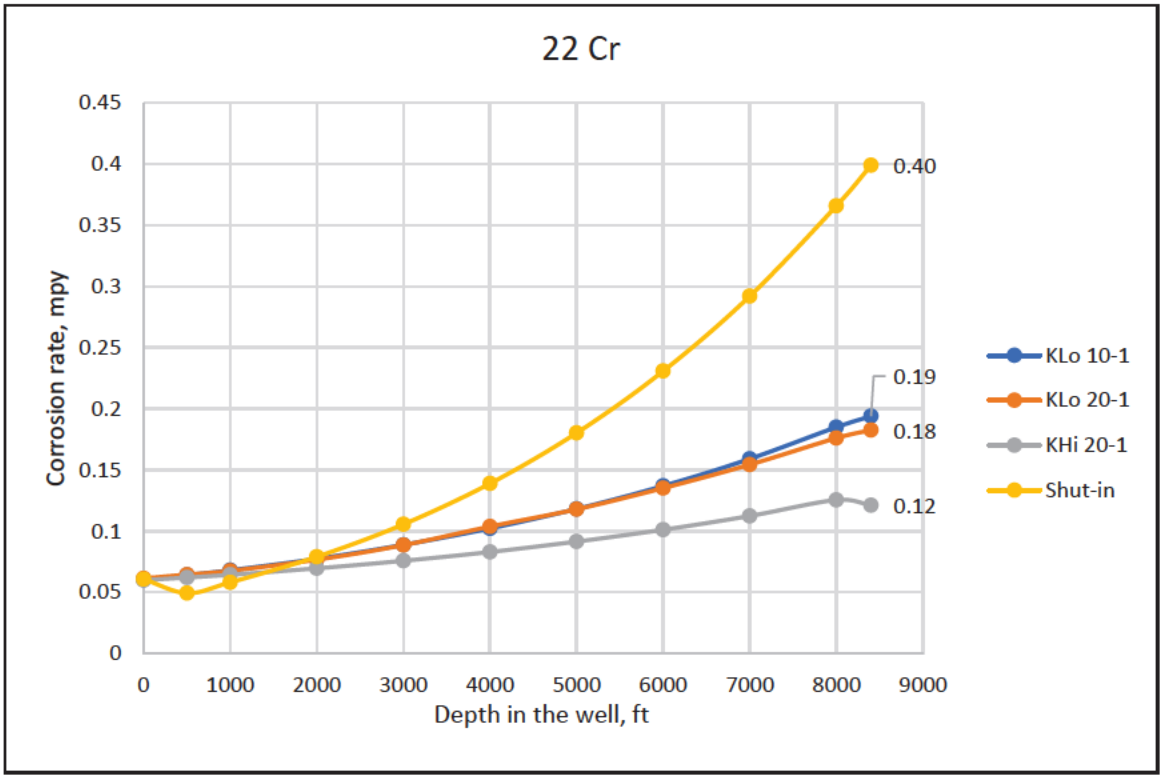

Figure 41: Corrosion of 22 Cr in the Aqueous Phase from Pre-Combustion Injectate

33 MMscf/D Combined Pre-combustion and Post-combustion Injection

The corrosion rate for combined pre-combustion and post-combustion injection streams was also determined. It was assumed that the pre-combustion injection stream at 10 MMscf/D mixes with 23 MMscf/D post-combustion injection stream. The mixing is done at a temperature of 94°F and a pressure of 2,000 psig using the saturator function in OLI. The corrosion rates were estimated at different temperature and pressure conditions.

Figure 42 shows the corrosion rate of modified 13Cr in the liquid phase formed from combined pre-combustion and post combustion injection streams. The maximum corrosion rate of modified 13Cr during injection is 1.04 mpy, and 3.56 mpy during shut-in. The corrosion rate of modified 13Cr in the liquid from combined pre-combustion and post combustion injection stream is slightly lower than the corrosion in the liquid forming from pre-combustion alone. This increase in corrosion rate may be attributed to the presence of elemental sulfur in the pre-combustion stream.

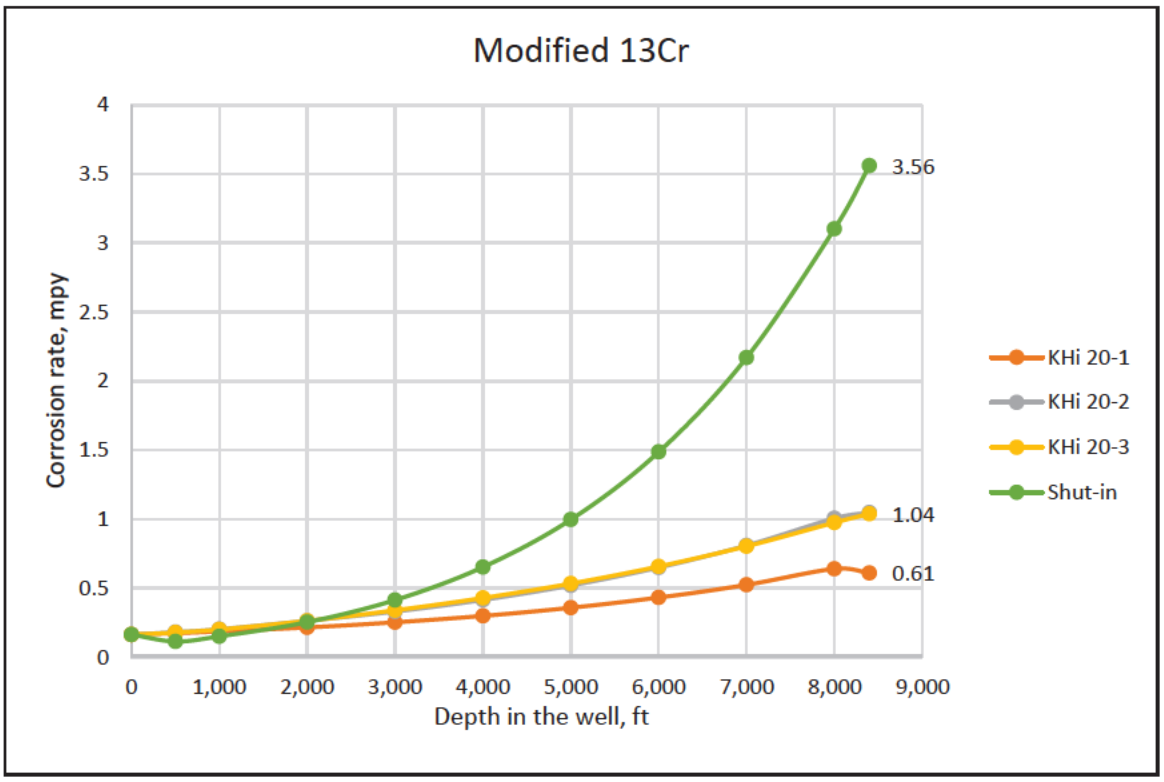

Figure 42: Corrosion of Modified 13 Cr in the Aqueous Phase from Mixture of Pre-Combustion and Post-Combustion Injectate (33 MMsdf/D)

Figure 43 shows the corrosion rate for 22Cr in the liquid water (aqueous) phase formed from the combined pre-combustion and post combustion injection streams. The corrosion rates were estimated based on the temperature and pressure conditions during injection and during shut-in. The highest corrosion rate occurs during shut-in. The estimated corrosion rate of 22Cr for the combined pre-combustion and post-combustion injection streams is slightly lower than the corrosion rate of 22Cr in the pre-combustion stream alone.

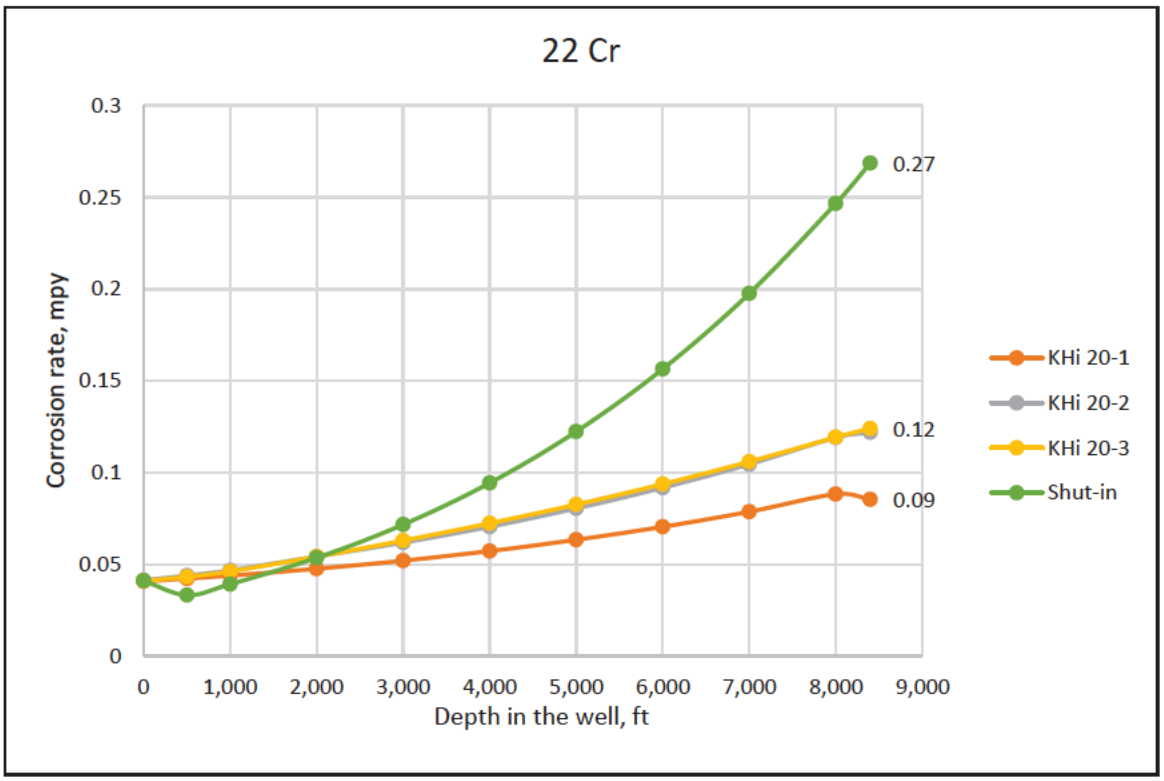

Figure 43: Corrosion of 22 Cr in the Aqueous Phase from Mixture of Pre-Combustion and Post-Combustion Injectate (33 MMscf/D)

80 MMscf/D Combined Pre-combustion and Post Combustion Injection

The corrosion rate for combined pre-combustion and post-combustion injection streams was also determined. It was assumed that the pre-combustion injection stream at 10 MMscf/D mixes with 70 MMscf/D post-combustion injection stream. The mixing was done at a temperature of 94°F and pressure of 2,000 psig using the saturator function in OLI. The corrosion rates were estimated at different temperature and pressure conditions.

Figure 44 shows the corrosion rate for modified 13 Cr in the liquid phase formed from combined pre-combustion and post combustion injection stream at 80 MMscf/D. The maximum corrosion rate for modified 13Cr during injection is 1.02 mpy, and 3.48 mpy during shut-in. Figure 45 shows the corrosion rate for 22 Cr in the liquid phase formed from a combined pre-combustion and post combustion injection stream at 80 MMscf/D. The maximum corrosion rate of modified 13Cr during injection is 0.11 mpy, and 0.23 mpy during shut-in. These estimated corrosion values are slightly lower compared to the corrosion at 33 MMscf/D total injection rate.

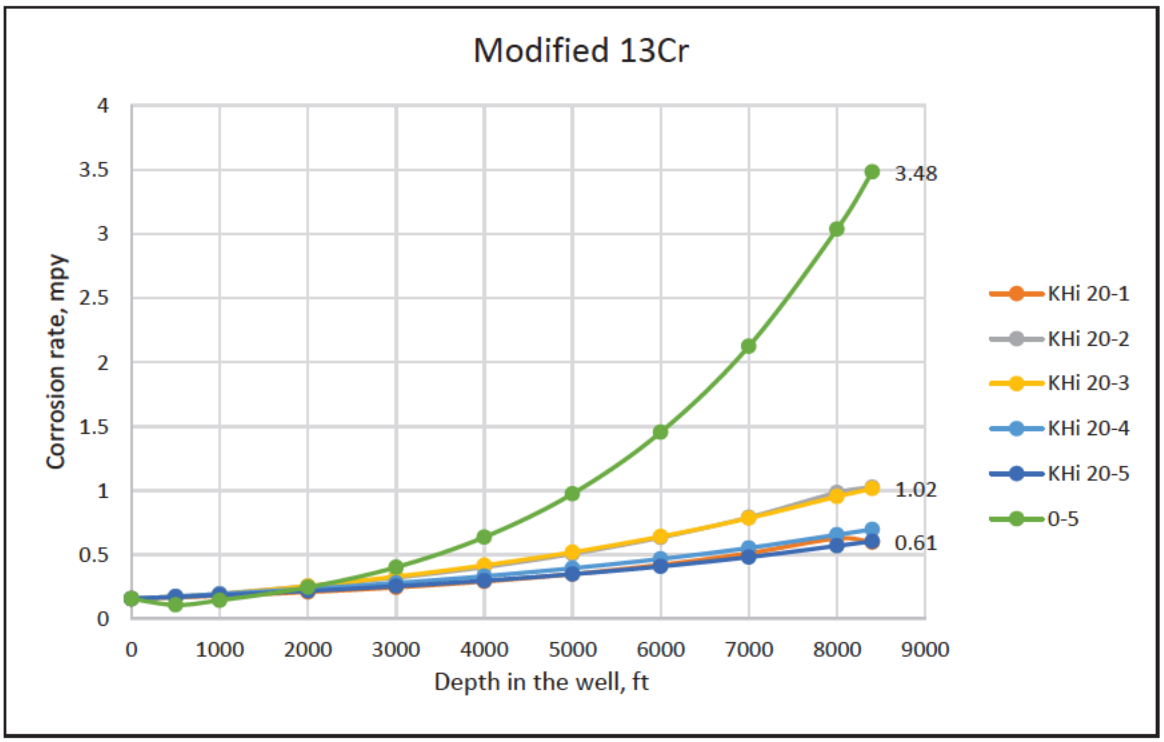

Figure 44: Corrosion of Modified 13 Cr in the Aqueous Phase from Mixture of Pre-Combustion and Post-Combustion Injectate (80 MMscf/D)

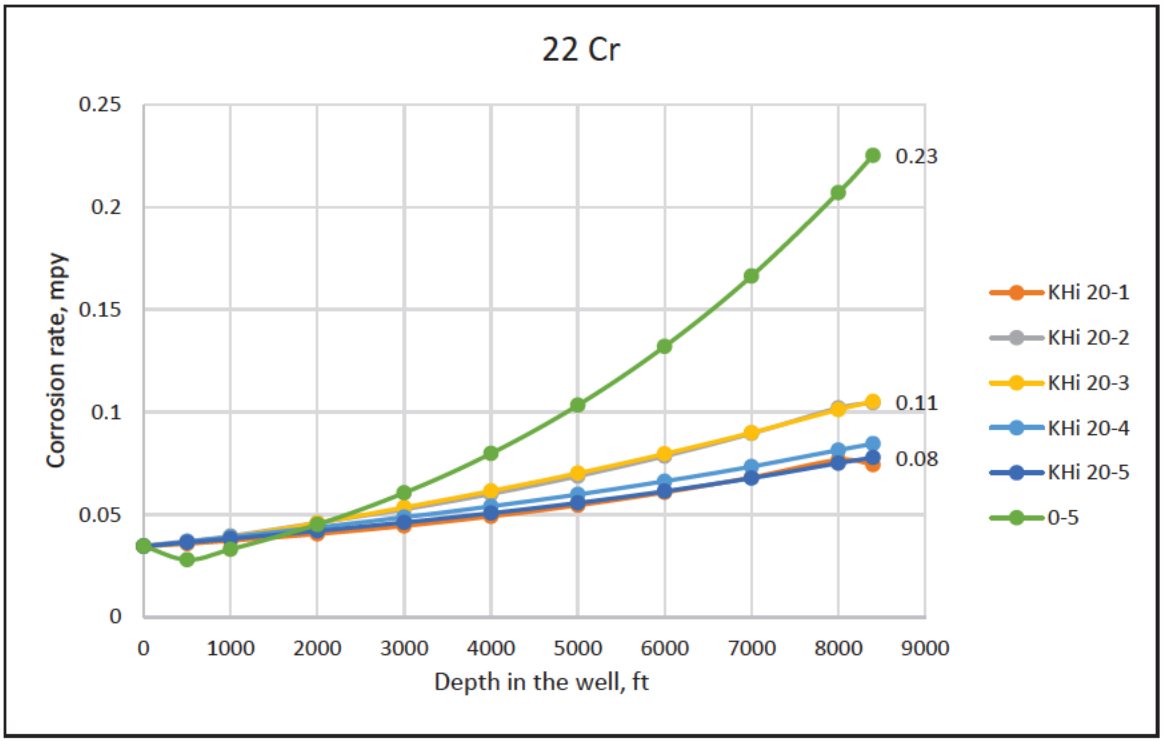

Figure 45: Corrosion of 22 Cr in the Aqueous Phase from Mixture of Pre-Combustion and Post-Combustion Injectate (80 MMscf/D)

5.3.3 Corrosion Due to Injected Gas Mixing with Reservoir Fluid

Upset conditions such as reservoir backflow during shut-in period or reservoir mixing with injection gas at the bottom of the well was also studied. Corrosion rates were predicted using a thermodynamic model of a case where injected gas mixes with the reservoir fluid. The reservoir fluid was modeled by using the brine composition listed in Table 20 and the gas composition listed in Table 21. The brine and the gas were mixed in the saturator function of OLI at temperature of 241°F and pressure of 4,125 psi. The stream has 69% gas saturation and 31% brine. The resulting mixture was used as the reservoir stream input to the thermodynamic model. The reservoir stream was mixed with pre-combustion stream and post combustion stream at the following ratios:

- 100 parts injection stream
- 1 part injection stream to 100 parts reservoir stream
- 50 parts injection stream to 50 parts reservoir stream
- 100 parts injection stream to 1 part reservoir stream

Table 20: Reservoir Brine Composition

Cations (mg/L)	
Na+1	11,000
K+1	210

CO_2	2.250

Component	Reconciled Gas (Mole %)
H_2S	7.00e-3
CH_4	96.013

The resulting mixture of the reservoir and the injectate has a pH range between 3.5 to 4.5, which is slightly higher than the pH of the injectate alone. Figure 46 shows the variation in the pH with the mixing ratio of the injectate stream and the reservoir stream.

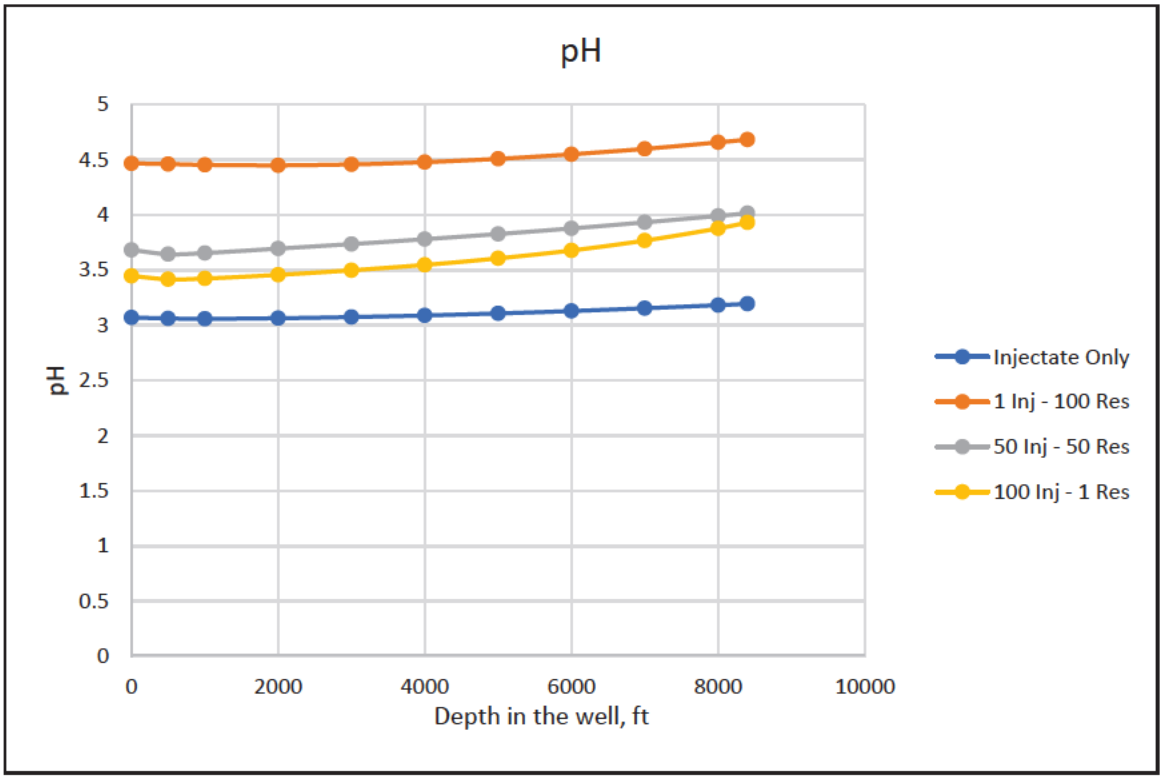

Figure 46: pH of Injectate and Reservoir Mixture

The corrosion rates were determined at different depths inside the injection well when the injectate mixes with the reservoir fluid at different volume ratios. Figure 47, Figure 48, Figure 49, Figure 50, and Figure 51 show the corrosion rate of carbon steel, 13Cr, modified 13Cr, modified 17Cr, and 22 Cr respectively. These corrosion rates were determined using only pre-combustion injection stream mixing with the reservoir fluid. The corrosion rates in pre-combustion injection stream together with post-combustion injection stream mixing with the reservoir fluid were also studied. However, the results were not presented here since the corrosion rates from these models were slightly lower than the corrosion rates presented in Figure 47 to Figure 51. Results show that the corrosion rate of the materials in the injection stream alone are highest compared to the corrosion in the injectate and reservoir mixture.

5.4 Well Construction Components

5.4.1 Metallic Components

The environment described in Table 19 was assumed to be exposed to these components. Further, depending on the type of well, the materials selection may vary. Table 22 shows the recommended materials.

The injection well components are expected to be exposed to CO_2 with water below the solubility limit. Any reservoir ingress would be further down in the well. Consequently, the recommendation for the tree and its components is F6NM a martensitic stainless steel. However, further down in the well there is a risk of CO_2 and other components being wet due to the reservoir fluids; consequently, components are recommended to be precipitation hardened nickel-based alloys, such as Alloy 718.

The observation wells may be exposed to CO_2 and the impurities along with reservoir water all the way to the surface. Consequently, the tree is recommended to be F22 material clad with Alloy 625. The lower completion equipment materials should be Alloy 718, a precipitation hardened nickel alloy.

Table 22: Summary of Materials Recommendations for Injection and Observation Wells

Well Type	Components	Recommended Material
Injection	Flow wetted wellhead components (tree valves, flow cross, tubing hanger, etc.)	F6NM
Injection	CRA material for tubing, casing, and liners	Modified 13Cr
Injection	Packer and downhole components	Alloy 718

Well Type	Components	Recommended Material
Observation	Flow wetted wellhead components (tree valves, flow cross, tubing hanger, etc.)	F22 with Alloy 625 Clad
Observation	CRA material for tubing, casing, and liners	Modified 13Cr
Observation	Packer and downhole components	Alloy 718 or equivalent
Injection and Observation	Elastomer for tubing hanger seals (1)	HNBR/Teflon/PEEK
Injection and Observation	Elastomer for packer element (1)	EPDM
Injection and Observation	Elastomer for other downhole seals (1)	HNBR/Teflon/PEEK
Notes: (1) All seals should be evaluated for rapid gas decompression (RGD) capability. No chemical reaction is expected for this type of material with dense phase CO_2.		

5.4.2 Elastomers

The small cross section seals can be sourced from a proven rapid gas decompression (RGD) resistant seal set of a combination of HNBR, PTFE and PEEK (as the tool's seal design requires). These materials will be stable at the expected temperature, pressure, and chemical make-up of the fluid to be injected, including a small amount of H_2S. O-rings, depending on the equipment design may or may not have a back-up ring. If those are in the design, 25% GF PTFE should be adequate at the given temperature and pressure and in some cases a virgin or 30% GF (glass filled) PEEK can also be used. For the packer element, the primary recommendation is EPDM as the wells are primarily CO_2 injection with minor amounts of impurities. EPDM does very well in CO_2 applications and is one of the better materials in resisting expansion after CO_2 pressure is released, i.e., after the packer is unset and pulled from the well. A proven RGD resistant material HNBR is an option as well for the packer element.

5.5 Discussion

Experimental results published in the literature show that the corrosion of carbon steel and corrosion resistant alloys (CRA) in super critical CO_2 are very low. Some papers report corrosion rates of 1.2 – 1.7 mpy (33 – 43 µm/yr) for carbon steel and 0.1 – 0.35 mpy (3 – 9 µm/yr) for 13Cr when the water phase is in equilibrium with super critical CO_2 phase (water entrained in the super critical CO_2 phase) [5]. The corrosion rate of carbon steel in dry supercritical CO_2 is very low, which is generally observed in the field. Pipelines in service with high pressure dry CO_2 have corrosion rates between 0.02 – 0.1 mpy (0.5 – 2.5 µm/yr) [5] [8] [9] [10]. Very high corrosion rates of carbon steel up to 79 mpy (2 mm/yr) in super critical CO_2 with low amount of dissolved water were also reported in the literature [11] [12]. Authors have argued that these very high corrosion rates are most likely artifacts of the experimental procedure [11].

Based on published data, the corrosion rate of carbon steel and 13Cr can be as high as 197 – 551 mpy (5 – 14 mm/yr) and 11 – 32 mpy (0.3 – 0.8 mm/yr), respectively, only when the water phase precipitates out of the super critical CO_2 [5]. These values are within the range of the thermodynamic prediction of

corrosion rates for carbon steel and 13Cr in the liquid water (aqueous) phase precipitating from the injection stream.

Literature also reports the corrosion rates of carbon steel and CRAs in aqueous phase that precipitate out of the dense CO_2 stream containing impurities including SO_2, NO_2, H_2S, O_2. Xiang et al., provided a summary of corrosion rates based on available literature [13]. The reported corrosion rates are generally smaller compared to the results of the thermodynamic modeling.

Results of the thermodynamic modeling show that the corrosion rate of materials in the liquid water (aqueous) phase forming from the pre-combustion stream alone is higher than the electrolyte forming when pre-combustion is mixed with post-combustion stream. This can be due to the presence of elemental sulfur in the pre-combustion injection stream.

The formation of elemental sulfur has been discussed in the literature. However, there is a lack of understanding on the exact formation mechanism for elemental sulfur and how it affects the corrosion of materials. Several possible chemical reactions have been presented in the literature; some are listed below. Elemental sulfur can be produced when H_2S interacts with O_2 as shown in equation 1 [14] or when H_2S and SO_2 interacts based on equation 3 below. Elemental sulfur and SO_2 can be produced with H_2S and O_2 or NO_2 reactions, which can create more H_2SO_4 and H_2SO_3 based on equations 4, 5 and 8 listed below, which can create a more acidic environment. When the elemental sulfur remains dissolved in the bulk dense CO_2 phase, authors have indicated that it will probably not cause problems, but if it precipitates as a solid, it may create a particulate problem [15] or possibly enhance corrosion or cause pitting [16] [17] [18]. Results of the thermodynamic model did not predict the formation of pits for 13Cr, modified 13Cr, modified 17 Cr and 22 Cr. Further testing will be needed to look at the effect of elemental sulfur formation as well as the oxidized compounds of sulfur.

$$2\ H_2S + 2\ O_2 \rightarrow 2\ H_2O + 1/n\ S_n + SO_2 \quad (1)$$

$$2\ H_2S + SO_2 \rightarrow 3/x\ S_x + 2\ H_2O \quad (2)$$

$$H_2S + 2\ NO_2 \rightarrow ½\ SO_2 + 2\ NO + H_2O + ½\ S \quad (3)$$

$$NO_2 + SO_2 + H_2O \rightarrow NO + H_2SO_4 \quad (4)$$

$$SO_2 + ½\ O_2 + H_2O \rightarrow H_2SO_4 \quad (5)$$

$$H_2S + H_2SO_4 \rightarrow S + SO_2 + 2\ H_2O \quad (6)$$

$$H_2S + HNO_3 \rightarrow 3S + 2\ NO + 4\ H_2O \quad (7)$$

$$SO_2 + H_2O \rightarrow H_2SO_3 \quad (8)$$

5.6 Conclusions

The key conclusions from thermodynamic modeling and literature review are as follows:

- Liquid water (aqueous) phase may precipitate when the amount of water goes beyond the solubility limit. This may occur during upset conditions or shut-in conditions.
- Corrosion of materials in dense phase CO_2 undersaturated water is minimal, but corrosion in the liquid water (aqueous) phase formed from the injection stream is extremely high for carbon steel and 13Cr.
- Modified 13Cr exhibits a corrosion rate of ~1.3 mpy during injection and ~3.7 mpy during shut-in conditions. 22Cr has the lowest corrosion rate during injection and shut-in for the materials evaluated.

- Based on the assumed compositions for the injectate and reservoir, modified 13 Cr is adequate for this application.
- The presence of elemental sulfur from the pre-combustion injection stream, and from the reaction of the impurities in the injection stream may cause further increase in the corrosion rate predicted by the models, driving the selection of higher grades (22Cr). Assessment of the chosen alloy, either modified 13Cr or 22Cr, would require testing in the presence of sulfur to investigate corrosion and possibly cracking.

6 Injection Wells Design and Analysis

6.1 Design Approach

6.1.1 Working Stress Design Factors

Working stress design (WSD) is the traditional method of casing and tubing design used commonly for oil and gas well design. It is the basis of design for the current work. Load and stress analysis were performed using StrinGnosis, a commercial tubular mechanics and thermal analysis program. Loads and strengths were determined and used to compare the loads to the pipe strength. A safety factor was calculated as the ratio of the (minimum) strength to the (conservatively estimated) load and was compared to a minimum safety factor, also referred to as the design factor. Table 23 shows the design factors (minimum safety factors) that were used for the WSD analysis.

Table 23: Aera Design Factors

Failure Mode	Casing	Tubing (6)	Loss of Containment
Triaxial	1.25	1.25	1.00
Burst	1.30	1.20	1.00
Collapse	1.00	1.10	1.00
Axial – Tension	1.60	1.40	1.00
Axial – Compression	1.40	1.40	1.00

The Aera burst design factor of 1.30 and tension DF of 1.60 are higher than the DFs used by many oil and gas operators. Table 24 shows typical industry design factors for comparison. The design results will be evaluated using the Aera DFs and if the safety factors are less than Aera's DFs, the results will be compared to the typical design factors. Implications of the DFs will be discussed in the design report results.

Table 24: Typical Industry Design Factors

Failure Mode	Casing	Tubing (6)	Loss of Containment
Triaxial	1.25	1.25	1.00
Burst	1.10	1.20	1.00
Collapse	1.00	1.10	1.00
Axial – Tension	1.40	1.40	1.00
Axial – Compression	1.40	1.40	1.00

6.1.2 Reliability Based Design

Designs that do not meet the design factor requirements will be evaluated using Reliability Based Design (RBD) methods to determine the probability of failure (POF) or probability of exceedance (POE), i.e., yielding but not failing the pipe body. RBD Level 4 analysis for isotropic material is part of StrinGnosis, the program used for design analysis. Section 9 provides an overview of RBD. In Level 4 RBD, the load is assumed as deterministic at the extreme magnitude used in WSD, while the strength is stochastic. The

probability distribution of strength is constructed from statistical data on the underlying strength parameters, which are in turn obtained from ISO TR 10400 (API TR 5C3), or manufacturer data where possible. The design criteria for RBD are shown in Table 25.

Table 25: Level-4 RBD Design Criterion

Failure Mode and Load Type	Minimum Design Criterion
Probability of Exceedance (VME)	
Service Loads	$\leq 10^{-4}$
Survival Loads	$\leq 10^{-3}$
Probability of Failure (Burst-Tension)	
Service Loads	$\leq 10^{-6}$
Survival Loads	$\leq 10^{-5}$
Probability of Failure (Collapse)	
Service Loads	$\leq 10^{-3}$
Survival Loads	$\leq 10^{-2}$

RBD analysis explicitly quantifies the risk of failure of a given design. It allows the risk to be compared between different designs, whereas WSD analysis would show a change in the safety factor but no quantitative assessment of the change in the risk of failure. RBD is commonly used in structural design codes for other industries. RBD has been implemented in casing design programs by constructing resistance distributions using limit state equations such as the Klever-Stewart Rupture Limit and the Klever-Tamano Collapse Limit and strength parameter data from API TR 5C3 (ISO TR 10400), manufacturer reports or direct material and dimensional measurements. In addition to the RBD overview in Section 9 in this document, more details on the concept and use of RBD can be found in the literature including *IADC/SPE-178907-MS A Reliability-Based Approach for Survival Design in Deepwater and High Pressure/High Temperature Wells* [19].

6.1.3 Annular Pressure Management (API RP 90-2)

Wells can be operated safely with sustained annulus casing pressure. API Recommended Practice 90-2 (RP 90-2) [20], *Annular Casing Pressure Management for Onshore Wells* provides recommendations for operating wells with annulus pressure. The recommended practice document defines the maximum allowable wellhead operating pressure (MAWOP) for an annulus.

RP 90-2 needs to be considered as part of the casing and tubing design for CCS wells because of the EPA requirement to maintain annulus pressure on CCS wells while injecting. Meeting RP 90-2 recommendations requires an evaluation of the annulus pressure loads compared to the API minimum internal yield pressure (MIYP) of the casing and minimum collapse pressure (MCP) of the tubing.

API RP 90-2 has several methods to determine the allowable annulus pressure. Two of the methods are appropriate for CO_2 injection wells.

Simple De-rating Method

A summary of the relevant derating and design factors for a CCS well with annulus pressure is as follows:

- 50% of the MIYP of the injection casing string being evaluated
- 75% of the MPC of the tubing string

For the MAWOP calculation, the safety factor takes into account the following considerations:

- The minimum pressure rating of the casing string (including couplings) as per API 5 CT
- Unknown erosion or corrosion of the pipe

Explicit De-rating Method

If the wall thickness measurements are available, this method can be used to evaluate the casing MIYP. A summary of the derating and design factors follows:

- 80% of the adjusted MIYP of the injection casing string
- 80% of the adjusted MCP of the tubing string
- 100% of the adjusted MIYP of the next outer tubular string

6.2 Design Load Cases

6.2.1 Summary of Design Pressures

Table 26 shows a summary of the key design pressures used in the analysis.

Table 26: Design Pressures

Description	Value	Comments
Maximum tubing injection pressure	2,800 psi	PROSPER Modeling
Maximum annulus surface pressure	2,900 psi	Regulatory requirement for annulus pressure greater than injection pressure
SITP with methane to surface	3,950 psi	PROSPER Modeling
SITP with CO_2 to surface	2,300 psi	PROSPER Modeling
Maximum reservoir pressure	4,340 psi at 7,007 ft	Email from CA Moran November 30, 2023

6.2.2 7 in. Injection Casing Load Cases

Table 27 shows the injection casing loads description with the internal and external pressure and temperature profiles. The injection casing is defined as the casing outside the injection tubing. The existing casing for repurposed wells will be evaluated using these loads to determine which wells may have casing with sufficient strength for casing loads caused by CCS operations. These loads will also be used to design inner casing strings.

Table 27: Injection Casing Loads Description

No.	Casing Load	Internal Pressure	External Pressure	Temperature Profile
1	Running	Zero surface pressure + drilling fluid hydrostatic pressure	Zero surface pressure + drilling fluid hydrostatic pressure	Geothermal
2	Overpull (100 kips)	Zero surface pressure + drilling fluid hydrostatic pressure	Zero surface pressure + drilling fluid hydrostatic pressure	Geothermal
3	Initial condition	Drilling fluid hydrostatic pressure	Mud density hydrostatic pressure to the TOC + cement density hydrostatic pressure to the shoe	Geothermal
4	Kick—Gas to Surface	Kick surface pressure based on the lessor of frac at shoe or gas to surface	Zero surface pressure + drilling fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Geothermal

No.	Casing Load	Internal Pressure	External Pressure	Temperature Profile
5	Drilling casing pressure	Surface pressure + drilling fluid hydrostatic pressure not to exceed 70% of MIYP.	Zero surface pressure + drilling fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Geothermal
6	Casing pressure for injection[iv]	Maximum surface injection pressure + 100 psi + packer fluid hydrostatic pressure	Zero surface pressure + drilling base fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Long term injection profile (lowest temperature)
7	Tubing leak—Injection	Maximum surface injection pressure + packer fluid hydrostatic pressure.	Zero surface pressure + drilling base fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Long term injection profile (lowest temperature)
8	Tubing leak—shut-in (CO_2)	SITP based on maximum reservoir pressure minus the injection stream composition gradient + packer fluid hydrostatic pressure	Zero surface pressure + drilling base fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Geothermal
9	Tubing leak—shut-in (CH_4)	SITP based on maximum reservoir pressure minus a methane gradient + packer fluid hydrostatic pressure	Zero surface pressure + drilling base fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Geothermal
10	Collapse evacuation	Zero pressure to top of fluid with up to full evacuation of packer fluid hydrostatic pressure to shoe	Original drilling fluid	Geothermal
11	Bullhead kill—Initial	500 psi + maximum surface injection pressure + packer fluid hydrostatic pressure	Zero surface pressure + drilling base fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Minimum long term injection profile
12	Bullhead kill—Final	500 psi + kill fluid hydrostatic pressure based on maximum BHP	Zero surface pressure + drilling base fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Bullhead kill injection profile for 2 casing volumes at 3 fps

[iv] The EPA requires the tubing-casing annulus pressure to be higher than the tubing injection pressure for monitoring purposes for Class IV wells.

No.	Casing Load	Internal Pressure	External Pressure	Temperature Profile
13	Loss of containment	50% evacuated with packer fluid below top of fluid	Original drilling fluid	–40°F at surface. Geothermal temperature at total depth.
14	Stimulation tubing leak	Stimulation surface pressure + packer fluid hydrostatic pressure	Zero surface pressure + drilling base fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Stimulation

6.2.3 Liner Loads

Table 28 shows the liner loads and descriptions to be used to evaluate the liner designs.

Table 28: Liner Loads Description

No.	Liner Load	Internal Pressure	External Pressure	Temperature Profile
1	Running at 2 ft/sec	Zero surface pressure + drilling fluid hydrostatic pressure	Zero surface pressure + drilling fluid hydrostatic pressure	Geothermal
2	Overpull (50 kips ≤4.5 in. OD 100 kips >4.5 in. OD)	Zero surface pressure + drilling fluid hydrostatic pressure	Zero surface pressure + drilling fluid hydrostatic pressure	Geothermal
3	Initial condition	Zero surface pressure + drilling fluid hydrostatic pressure	Wellbore fluid hydrostatic pressure to the TOC. Cement hydrostatic pressure to the shoe.	Geothermal
4	Pressure test	Surface pressure + internal fluid hydrostatic pressure not to exceed 70% of MIYP	Pore pressure at the previous shoe minus drilling fluid gradient to the TOL. Pore pressure below the previous shoe.	Geothermal
5	Injection Steady State	Maximum surface injection pressure + internal injection fluid hydrostatic pressure	Pore pressure at the previous shoe minus drilling fluid gradient to the TOL. Pore pressure below the previous shoe.	Long term injection profile
6	Bullhead kill—Initial	Surface pressure 500 psi + maximum surface injection pressure + injection fluid hydrostatic pressure	Pore pressure at the previous shoe minus drilling fluid gradient to the TOL. Pore pressure below the previous shoe.	Long term injection profile

No.	Liner Load	Internal Pressure	External Pressure	Temperature Profile
7	Bullhead kill—Final	Surface pressure 500 psi + kill fluid hydrostatic pressure	Pore pressure at the previous shoe minus drilling fluid gradient to the TOL. Pore pressure below the previous shoe.	Bullhead kill injection profile for 2 tubing volumes
8	Collapse evacuation	Up to full evacuation with 8.3 ppg internal fluid hydrostatic pressure	Original drilling fluid hydrostatic pressure	Geothermal
9	Stimulation	Stimulation surface pressure + stimulation fluid hydrostatic pressure	Pore pressure at the previous shoe minus drilling fluid gradient to the TOL. Pore pressure below the previous shoe.	Stimulation
10	Late life SITP CH_4 to surface	Maximum reservoir pressure minus a methane gradient to surface	Pore pressure at the previous shoe minus drilling fluid gradient to the TOL. Pore pressure below the previous shoe.	Geothermal
11	Late life SITP CO_2 to surface	Maximum reservoir pressure minus a CO_2 gradient to surface	Pore pressure at the previous shoe minus drilling fluid gradient to the TOL. Pore pressure below the previous shoe.	Geothermal

6.2.4 Tubing Loads

Table 29 shows the tubing loads for CCS wells. The loads include installation, operational, and upset loads that could occur during the life of the well. Injection of mixtures of CO_2 and methane were modeled in the production engineering program PROSPER to predict pressure and temperature profiles for the tubing under injection conditions. The pressure and temperature profiles were used in the tubing stress analysis. Most stress analysis programs do not have models to handle the phase behavior of CO_2, especially with impurities. Therefore, in this work, PROSPER was used to perform the PVT analyses for injection, shut-in, and blowout modeling. Results from the PROSPER modeling were used to construct the appropriate loads in StrinGnosis.

Table 29: Tubing Loads Description

No.	Tubing Load	Internal Pressure	External Pressure	Temperature Profile
1	Running	Zero surface pressure. Completion fluid hydrostatic pressure.	Zero surface pressure. Completion fluid hydrostatic pressure.	Geothermal
2	Overpull (50 kips OD ≤4.5 in. 100 kips OD >4.5 in.)	Zero surface pressure. Completion fluid hydrostatic pressure.	Zero surface pressure. Completion fluid hydrostatic pressure.	Geothermal
3	Initial Condition	Zero surface pressure. Packer fluid hydrostatic pressure.	Zero surface pressure. Packer fluid hydrostatic pressure.	Geothermal

No.	Tubing Load	Internal Pressure	External Pressure	Temperature Profile
4	Pressure test	Surface test pressure + packer fluid hydrostatic pressure	Zero surface pressure. Packer fluid hydrostatic pressure.	Geothermal
5	A-annulus pressure test—maximum surface injection pressure	Zero surface pressure + packer fluid hydrostatic pressure	Maximum surface injection pressure + packer fluid hydrostatic pressure	Geothermal
6	Injection Steady State	Maximum surface injection surface pressure + injection fluid pressure profile	Zero surface pressure. Packer fluid hydrostatic pressure.	Long term injection profile
7	Late life SITP CH_4 to surface	Maximum reservoir pressure minus the natural gas gradient to surface	Zero surface pressure. Packer fluid hydrostatic pressure.	Geothermal
8	Late life SITP CO_2 to surface	Maximum reservoir minus a CO_2 gradient to surface	Zero surface pressure. Packer fluid hydrostatic pressure.	Geothermal
9	Tubing leak below SCSSV with SCSSV closed	Zero psi to SCSSV. Maximum reservoir pressure minus a CO_2 gradient below the closed valve	Surface pressure based on maximum reservoir pressure + packer fluid hydrostatic pressure	Geothermal
10	Tubing evacuation (zero annulus pressure)	Up to full evacuation with 8.3 ppg internal fluid	Zero surface pressure + packer fluid hydrostatic pressure	Geothermal
10 a	Tubing evacuation (operating annulus pressure)	Up to full evacuation with 8.3 ppg internal fluid	Operating surface pressure + packer fluid hydrostatic pressure	Geothermal
11	Bullhead kill—Initial	500 psi above the maximum surface injection pressure + injection fluid pressure profile	Zero surface pressure + packer fluid hydrostatic pressure	Long term injection profile
12	Bullhead kill—Final	500 psi surface pressure + kill fluid hydrostatic pressure	Zero surface pressure + packer fluid hydrostatic pressure	Bullhead kill injection profile for 2 tubing volumes at 3 fps velocity
13	Loss of containment CO_2	Pressure from PROSPER based on the injection stream composition at maximum reservoir pressure	Zero surface pressure + packer fluid hydrostatic pressure	PROSPER analysis
14	Transient Startup	Initial surface injection pressure + internal injection fluid pressure	Zero surface pressure + packer fluid hydrostatic pressure	–4°F at Surface. Early life injection temperature lower 2/3 of MD.

No.	Tubing Load	Internal Pressure	External Pressure	Temperature Profile
15	Stimulation	Stimulation surface pressure + stimulation fluid hydrostatic pressure	Zero surface pressure + packer fluid hydrostatic pressure	Stimulation

6.2.5 Drilling Casing Loads

Table 30 shows the drilling casing loads description with the internal and external pressure and temperature profile. The drilling casing is defined as the casing above the injection casing.

Table 30: Drilling Casing Loads Description

No.	Casing Load	Internal Pressure	External Pressure	Temperature Profile
1	Running at 2 ft/sec	Zero surface pressure + drilling fluid hydrostatic pressure	Zero surface pressure + drilling fluid hydrostatic pressure	Geothermal
2	Overpull (100 kips)	Zero surface pressure + drilling fluid hydrostatic pressure	Zero surface pressure + drilling fluid hydrostatic pressure	Geothermal
3	Initial condition	Mud density hydrostatic pressure	Mud density hydrostatic pressure to the TOC + cement density hydrostatic pressure to the shoe	Geothermal
4	Kick—Gas to Surface	Kick surface pressure based on the lessor of frac at shoe or reservoir pressure gas to surface	Zero surface pressure + drilling fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Geothermal
5	Drilling casing pressure	Surface pressure + drilling fluid pressure not to exceed 70% of MIYP	Zero surface pressure + drilling fluid pressure to TOC + mix water pressure to previous shoe. Pore pressure below previous shoe.	Geothermal
6	Collapse 50% evacuation	Zero pressure to the top of fluid. Drilling fluid pressure to the shoe.	Original drilling fluid.	Geothermal

6.3 Remaining Wall Thickness Results Summary

This section includes a summary of the corrosion analysis and wall loss / remaining body wall (RBW) vs. time. The RBW results were used to evaluate the casing, liner, and tubing safety factors vs. time. The modeled RBW at 25 years of injection was used to confirm the designs are safe and reliable at the end of the injection phase. It is assumed that the injection wells will be plugged and abandoned within a year or two after injection stops.

The cumulative corrosion is based on a combination of injection and shut-in corrosion rates from the material selection study in Section 5. The corrosion rates used in the well design analysis are as follows:

- 1.3 mpy Injection corrosion rate
- 3.7 mpy Shut-in corrosion rate

Shut-in periods assume the following for routine maintenance and unplanned shut-ins:

- Shut-in 10 days per year for routine maintenance
- Shut-in 30 days per 15 year period or partial 15 year period for unplanned shut-ins

6.3.1 3 1/2 in. 9.2 ppf Liner

Table 31 shows the RBW for 3 1/2 in. OD 9.2 ppf 0.254 in. wall thickness based on years of service. The corrosion modeling wall loss results are based on the temperature and pressure at the liner. Year 25 is assumed as the end of injection.

Table 31: Corrosion RBW vs. Time for 3 1/2 in. 9.2 ppf Modified 13Cr

Year	Cumulative Corrosion (mils)	Wall Loss (in.)	RBW (%)	Remaining Wall (in.)	RBW (%)
–	–	–	Nominal	0.2540	100.00
0	0	–	87.50%	0.2223	87.50
25	35.6	0.0356	–	0.1866	73.5

6.3.2 4 1/2 in. 11.6 ppf Tubing

Table 32 shows the RBW for the 4 1/2 in. OD 11.6 ppf 0.250 in. wall thickness tubing based on years of injection. The corrosion modeling wall loss results are based on the temperature and pressure at the bottom of the tubing. Year 25 is assumed as the end of injection.

Table 32: Corrosion RBW vs. Time for 4 1/2 in. 11.6 ppf Modified 13Cr

Year	Cumulative Corrosion (mils)	Wall Loss (in.)	RBW (%)	Remaining Wall (in.)	RBW (%)
–	–	–	Nominal	0.2500	100.00
0	0	–	87.50%	0.2188	87.50
25	35.6	0.0356	–	0.1831	73.2

6.3.3 4 1/2 in. 12.6 ppf Liner

Table 33 shows the RBW for 4 1/2 in. OD 12.6 ppf 0.271 in. wall thickness based on years of service. The corrosion modeling wall loss results are based on the temperature and pressure at the liner. Year 25 is assumed as the end of injection.

Table 33: Corrosion RBW vs. Time for 4 1/2 in. 12.6 ppf Modified 13Cr

Year	Cumulative Corrosion (mils)	Wall Loss (in.)	RBW (%)	Remaining Wall (in.)	RBW (%)
–	–	–	Nominal	0.2710	100.00
0	0	–	87.50%	0.2371	87.50
25	35.6	0.0356	–	0.2015	74.3

6.3.4 6 5/8 in. 24 ppf Casing

Table 34 shows the RBW for 6 5/8 in. OD 24.0 ppf 0.352 in. wall thickness based on years of service. The corrosion modeling wall loss results are based on the temperature and pressure at the liner. Year 25 is assumed as the end of injection.

Table 34: Corrosion RBW vs. Time for 6 5/8 in 24 ppf Modified 13Cr

Year	Cumulative Corrosion (mils)	Wall Loss (in.)	RBW (%)	Remaining Wall (in.)	RBW (%)
–	–	–	Nominal	0.3520	100.00
0	0	–	87.50%	0.3080	87.50
25	35.6	0.0356	–	0.2724	77.4

6.3.5 7 in. 26 ppf Casing

Table 35 shows the RBW for 7 in. OD 26 ppf 0.362 in. wall thickness based on years of service. The corrosion modeling wall loss results are based on the temperature and pressure at the bottom of the casing. Year 25 is assumed as the end of injection.

Table 35: Corrosion RBW vs. Time for 7 in. 26 ppf Modified 13Cr

Year	Cumulative Corrosion (mils)	Wall Loss (in.)	RBW (%)	Remaining Wall (in.)	RBW (%)
–	–	–	Nominal	0.3620	100.00
0	0	–	87.50%	0.3168	87.5
25	35.6	0.0356	–	0.2811	77.7

6.3.6 7 in. 29 ppf Casing

Table 36 shows the RBW for 7 in. OD 29 ppf 0.408 in. wall thickness based on years of service. The corrosion modeling wall loss results are based on the temperature and pressure at the bottom of the casing. Year 25 is assumed as the end of injection.

Table 36: Corrosion RBW vs. Time for 7 in. 29 ppf Modified 13Cr

Year	Cumulative Corrosion (mils)	Wall Loss (in.)	RBW (%)	Remaining Wall (in.)	RBW (%)
–	–	–	Nominal	0.408	100.00
0	0	–	87.50%	0.357	87.5
25	35.6	0.0356	–	0.321	78.8

6.3.7 9 5/8 in. 47 ppf Casing

Table 37 shows the RBW for 9 5/8 in. OD 47 ppf 0.472 in. wall thickness based on years of service. The corrosion modeling wall loss results are based on the temperature and pressure at the liner. Year 25 is assumed as the end of injection.

Table 37: Corrosion RBW vs. Time for 9 5/8 in 47 ppf Modified 13Cr

0	0	–	87.50%	0.4130	87.50
25	35.6	0.0356	–	0.3774	79.9

6.4 PROSPER Analysis for Well Design Loads

6.4.1 7 in. Casing x 4 1/2 in. Tubing Completions

PROSPER flow modeling was used to develop the pressure and temperature profiles for the casing and tubing load cases. Well conditions include injecting, shut-in with CO_2 and CH_4 to surface, and loss of containment (blow-out). Figure 52 shows the injection temperature and pressure profiles for injecting 20 MMscf/D in an injection well with 4 1/2 in. tubing.

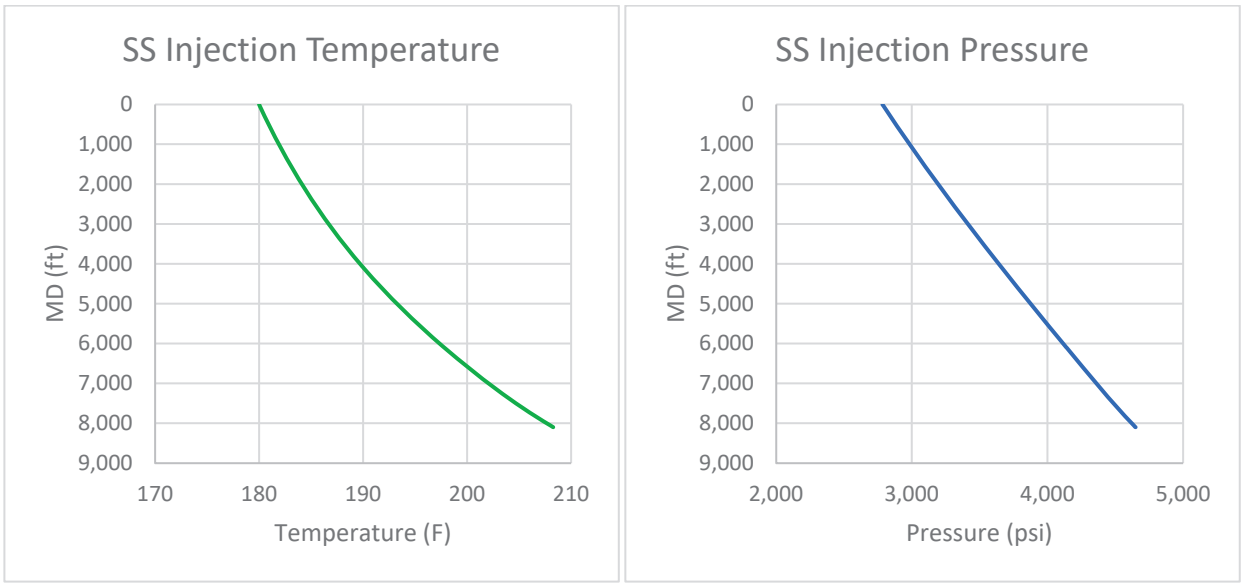

Figure 52: CO_2 Injection Temperature and Pressure Profiles for 20 MMscf/D for a 4 1/2 in. Completion

Figure 53 shows the pressure profiles for shut-in wells with a column of CO_2 and CH_4 based on the final reservoir pressure.

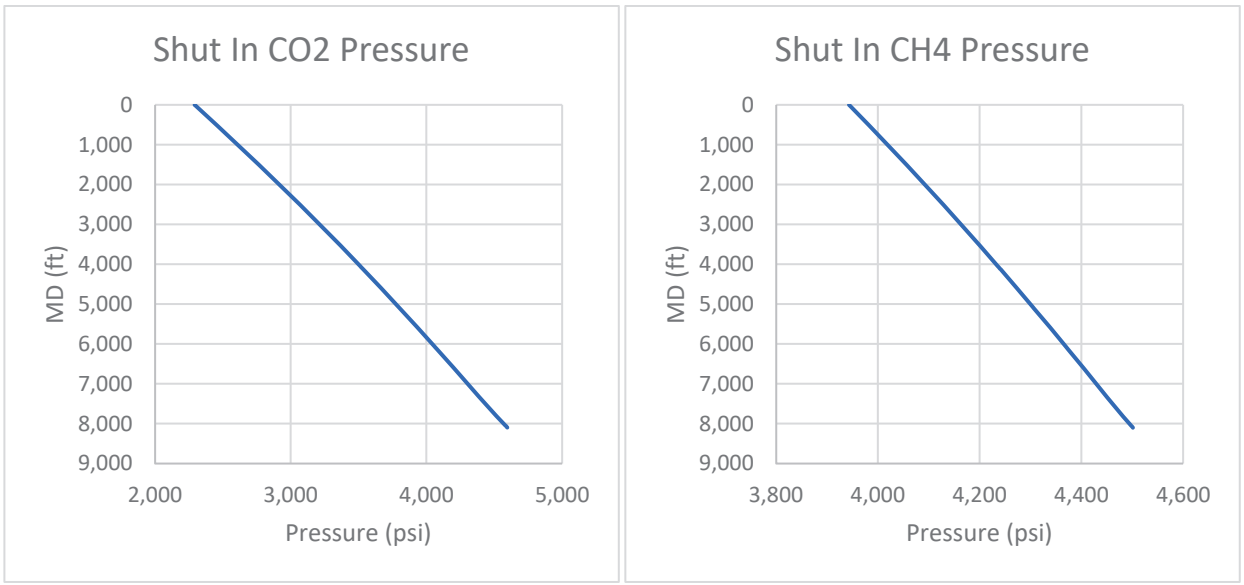

Figure 53: Pressure Profiles for Shut-in CO_2 (left) and CH_4 (right)

Figure 54 shows the temperature profile for loss of containment (blow-out) for CO_2 based on the final reservoir pressure.

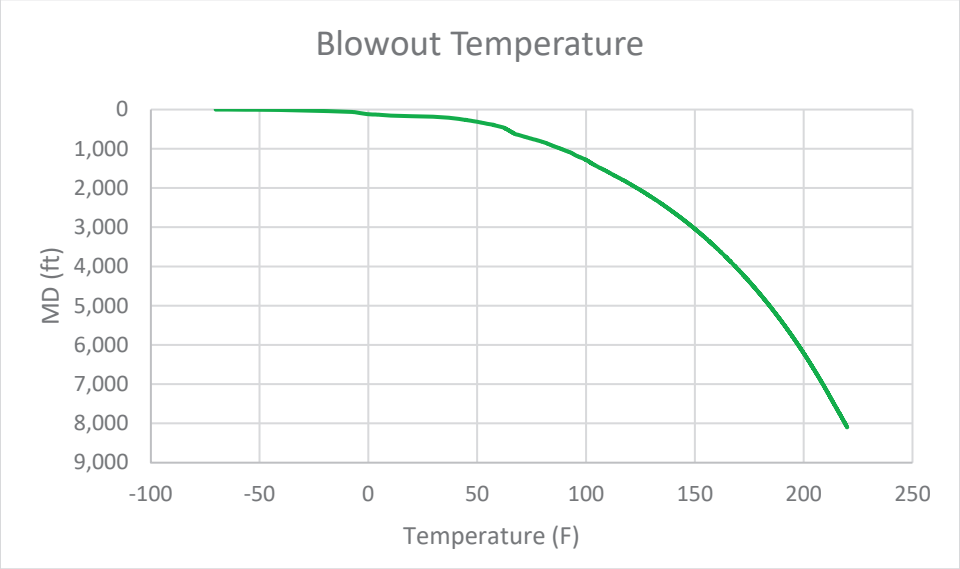

Figure 54: Pressure Profiles for Loss of Containment CO_2

6.5 Well 9-1N Repurposed Well Design

The proposed repurposed wells have similar casing setting depths and packer depths. Well 9-1N was evaluated in detail for all casing, liner, and tubing loads. The design results for 9-1N apply to the other wells where the casing OD is the same. The repurposed wells have different liner sizes and some are cased hole liners and some are open hole liners. Open hole liners were evaluated using the new drill well loads which are open hole liners. The tubing design is the same for repurposed and new drill wells.

Figure 55 shows the 9-1N wellbore after repurposing to a CO_2 injector. A new 7 in. inner casing with a section of CRA casing on bottom is proposed to isolate the existing 9 in. casing. The well has a cemented liner and a CRA inner liner is proposed to isolate the carbon steel liner. The completion includes a packer and CRA tubing to isolate the injected CO_2 from the casing. Monitoring equipment including fiber optic cable and downhole gauges are indicated.

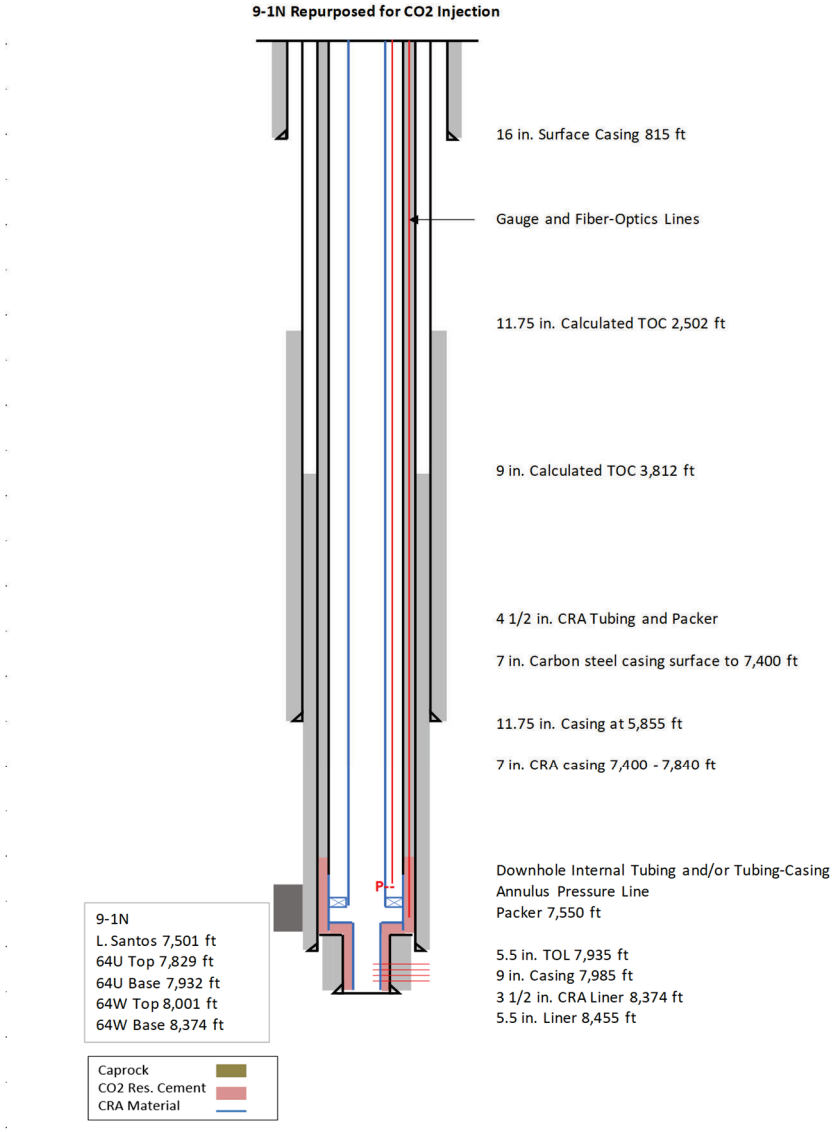

Figure 55: 9-1N Repurposed to CO_2 Injection Wellbore Schematic

6.5.1 Design Details and Assumptions

Table 38 shows the existing casing details, the proposed inner casing and liner and the proposed tubing design in rows 1 – 9. The design depths for the casing, liner, and tubing are approximate and can be adjusted based on requirements for the final well construction and completion depths.

A 3 1/2 in. OD liner is planned to isolate the existing liner in 9-1N. The inner liner will cover the existing perforations. It will be cemented with CO_2 resistant cement. The corrosion rate modeling summary results are included in Section 6.3. Row 10 shows the 4 1/2 in. liner details for repurposed wells with an inner liner for cementing inside an existing liner. Row 11 shows the design for an open hole liner.

Table 38: 9-1N Casing, Liner, and Tubing

Row	Name	Type	OD (in.)	Weight (ppf)	ID (in.)	WT (in.)	Grade	Conn.	Top MD (ft)	Bottom MD (ft)

9	Injection	Tubing	4.5	11.6	4.000	0.250	Mod 13Cr80	Proprietary (1)	0	7,550
10	Injection	Liner (2)	4.5	11.6	4.000	0.250	Mod 13Cr80	Proprietary (1)	7,930	8,374
11	Injection	Liner (3)	4.5	12.6	3.958	0.271	Mod 13Cr110	Proprietary (1)	7,930	8,374

Notes:
(1) Proprietary connection indicates a connection with a metal-to-metal seal and strengths equivalent to the pipe body.
(2) Liner design for an inner liner.
(3) Liner design for an open hole liner.

Directional Profile for 9-1N

The well was drilled as a vertical well.

Undisturbed Temperature Profile

The undisturbed temperature profile is shown in Section 11 Appendix C—Undisturbed Temperature Profile.

Pore Pressure and Fracture Pressure

The pore and fracture pressure data used in the analysis is included in Section 12 Appendix D—Pore Pressure.

Cementing

Cementing design assumptions are included in Section 13 Appendix E—Cementing Design Assumptions.

Completion and Packer Fluid

An unweighted clear fluid such as fresh water with 3% KCl (8.5 ppg) treated with inhibitors was assumed as the completion and packer fluid for design purposes.

6.5.2 9-1N Design Results

This section includes the results of the design analysis for the repurposed wells. The analysis includes the 7 in. inner casing, inner 3 1/2 in. and 4 1/2 in. liner, and 4 1/2 in. tubing. A CRA material grade was evaluated for the lower section of casing, liners, and tubing loads and is recommended to meet the requirements for limiting corrosion during the life of the well. Refer to Section 5 for details on materials selection.

7 in. Inner Injection Casing with Nominal Wall

Table 39 shows the minimum safety factors for the 7 in. L80 Section 1 casing loads. The load number corresponds to the load numbers in Section 6.2. The safety factors assume nominal wall thickness with a tolerance of –12.5% resulting in remaining body wall (RBW) of 87.5%. The minimum safety factors all meet or exceed the design factors shown in Table 23.

Table 40 shows the minimum SFs for Section 2. The SFs meet the DFs.

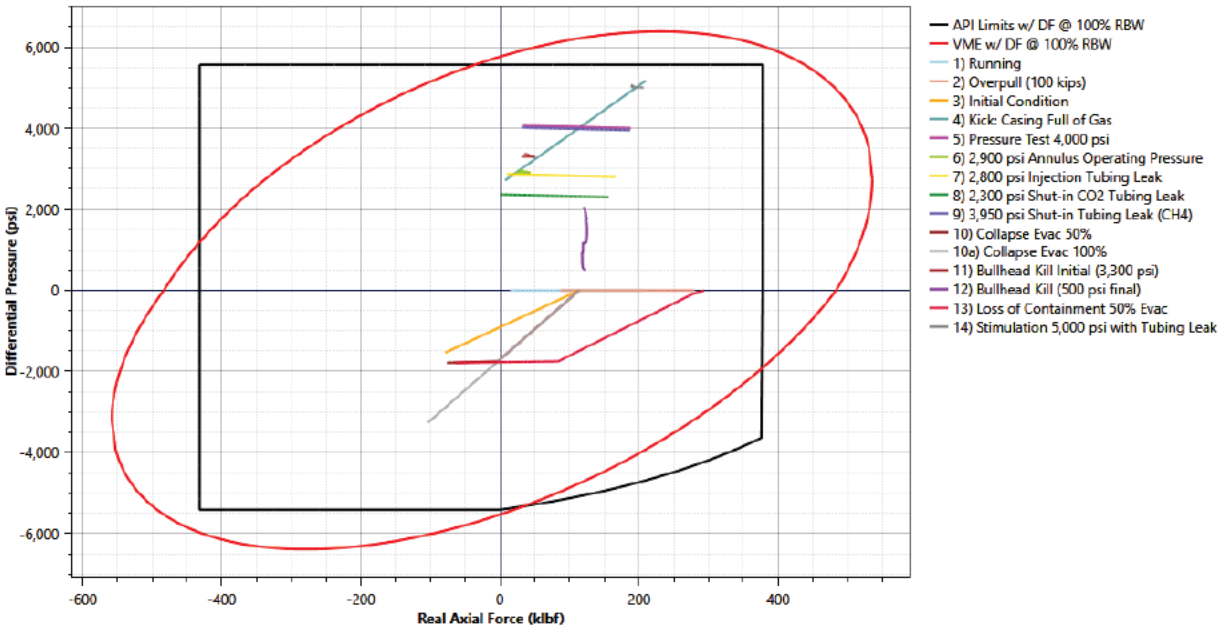

Figure 56: 7 in. Injection Casing with Nominal Wall Section 1 VME

Figure 57 shows the VME plot for the design loads.

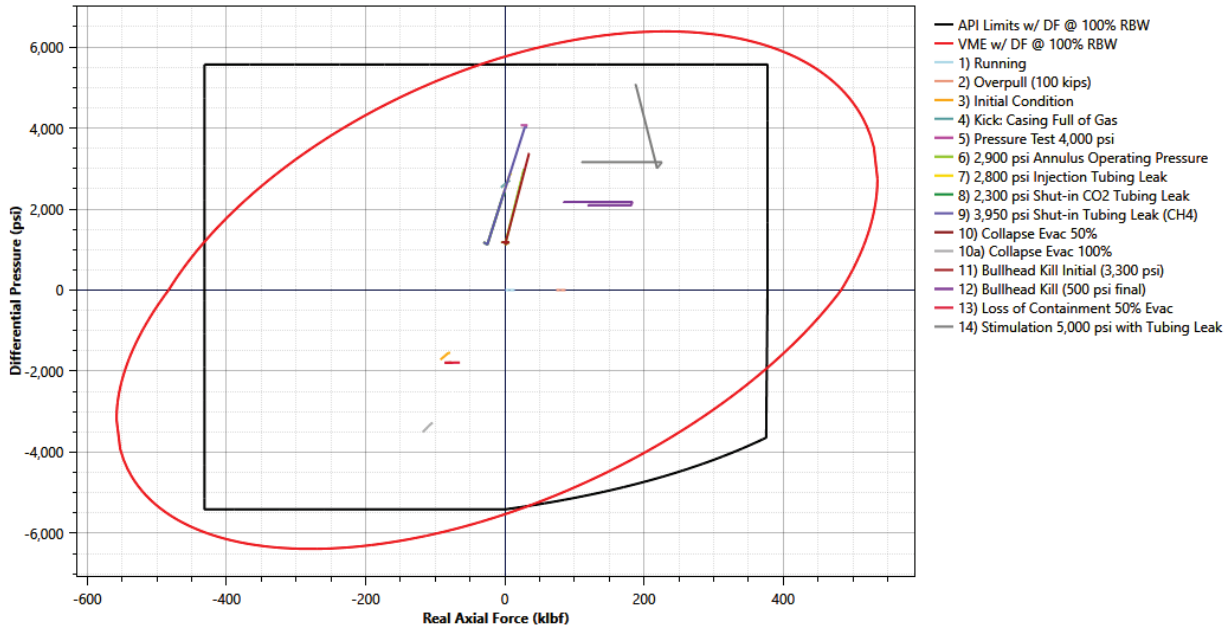

Figure 57: 7 in. Injection Casing with Nominal Wall Section 2 VME

7 in. Casing Wall with RBW 77.7% (25 years of service)

Table 41 shows the results for 77.7% RBW based on the wall loss shown in Section 6.3. Several loads have SFs less than the DFs. The SFs in red font are less than the DF for the load design failure mode.

The collapse SF is less than the DF of 1.00. Full evacuation of the casing after 25 years of service is an unlikely load and can be considered a design check for information. The stimulation load is an early life load and is not planned for late life. The results are shown for information.

Table 42 shows the RBD results. The load with high probability of failure is "10a) Collapse Evac 100%" which is not relevant to late life loads. The other loads meet the RBD acceptance shown in Table 76. The design meets the requirements for the relevant late life loads.

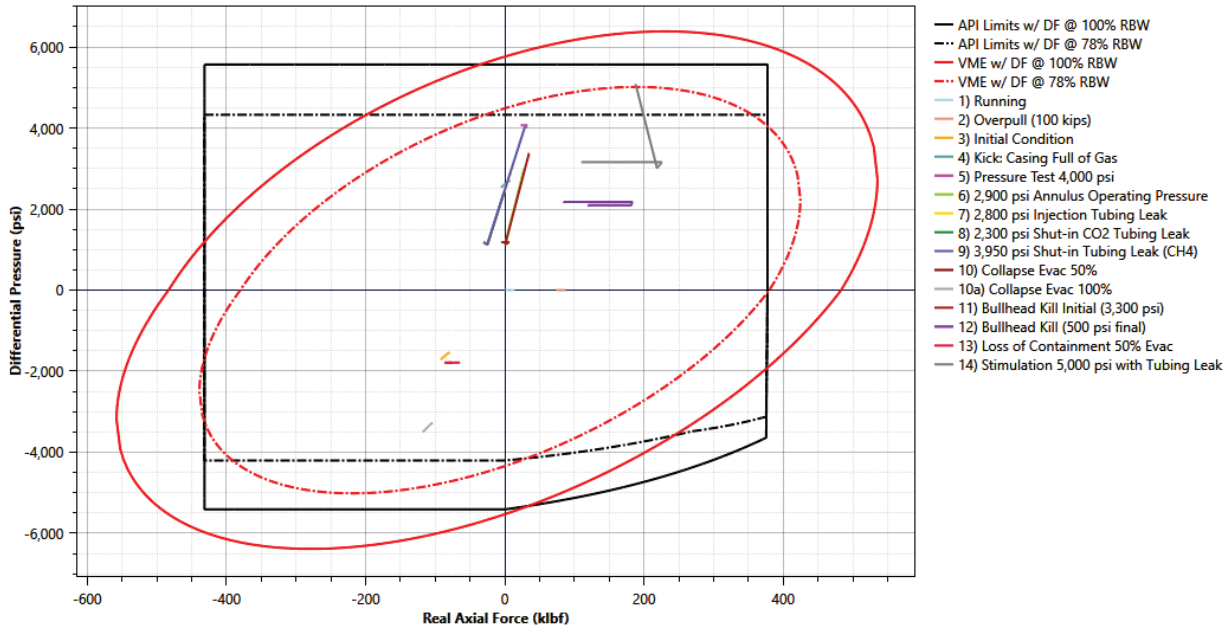

Figure 58: 7 in. Injection Casing with 77.7% RBW Section 2 VME

4 1/2 in. Tubing—New with 87.5% RBW

Table 43 shows the minimum safety factors for the 4 1/2 in. 11.6 ppf modified 13Cr80 tubing loads. New tubing was assumed with 87.5% remaining body wall (RBW). The safety factors exceed the design factors for the tubing design except for the load "10a) Collapse Evac 100% 2900 psi Ann Pr" which is an unlikely load that can be mitigated by managing and bleeding off the annulus pressure when the tubing pressure is reduced.

Table 44 shows the RBD analysis results. The RBD results do not meet the acceptance criteria so the annulus pressure needs to be managed.

4 1/2 in. Tubing—with 73.2% RBW (25 years of service)

The possible remaining wall at the end of 25 years of service for the 4 1/2 in. tubing is 73.2% of nominal based on wall loss from Section 6.3. Table 47 shows the minimum safety factors for the 4 1/2 in. 11.6 ppf modified 13Cr80 tubing loads, with 73.2% RBW. Several of the loads have SFs that are less than the DFs. However, the loads with low SFs are not realistic late life loads or can be easily mitigated. A summary of these unlikely loads follows in Table 46.

Table 48 shows the RBD results for information.

Table 46: Summary of Unlikely Loads

Load Name	Comments
5) 2,800 psi 'A' annulus pressure test	An annulus pressure test in late life is not a realistic load.
9) Tubing Leak Below SCSSV 2,900 psi CP 0 psi TP	The load can be managed by not bleeding off the internal tubing pressure in the event of a tubing leak.
10) Collapse Evac 100%	Full evacuation of the tubing is not realistic in late life and the annulus pressure must be managed and bled off when the tubing pressure is bled off.
10a) Collapse Evac 100% 2900 psi Ann Pr	Not a likely event and the annulus pressure must be managed and bled off when the tubing pressure is bled off.
14) Transient Startup	Not a late life load.
15) Stimulation 5,000 psi	Stimulation is not planned for late life.

The loads that are relevant in late life have acceptable safety factors and include the following:

- 6) Injection Steady State with 0 psi 'A' annulus pressure
- 7) Late life SI with CH_4 to surface
- 8) Late life SI with CO_2 to surface

In addition to the above discussion the tubing can be replaced if it is found to have a wall thickness that creates a risk. A periodic tubing inspection program is recommended to validate the corrosion modeling results.

6.6 Well 64-35N Repurposed Well Design

Well 64-35N has an un-cemented liner that will be removed leaving open hole through the injection zone. The well design is to run and cement 7 in. casing above the injection zone, set a 4 1/2 in. liner through the injection zone, and complete with 4 1/2 in. tubing.

Figure 66 shows the 64-35N wellbore after conversion to a CO_2 injector. A new 7 in. inner casing with a section of CRA casing on bottom is proposed to isolate the existing 9 in. casing with the 7 in. inner casing set near the shoe of the 9 in. casing. This design has a good chance of cementing the 7 in. casing to surface as required by the EPA and CARB because the low pressure injection zone can be temporarily isolated for running and cementing the 7 in. casing.

After the 7 in. inner casing is run and cemented, the open hole through the injection zone can be cleaned out and a 4 1/2 in. CRA liner can be run and cemented.

The completion includes a packer and CRA tubing to isolate the injected CO_2 from the casing. Monitoring equipment including fiber optic cables and downhole gauges are indicated.

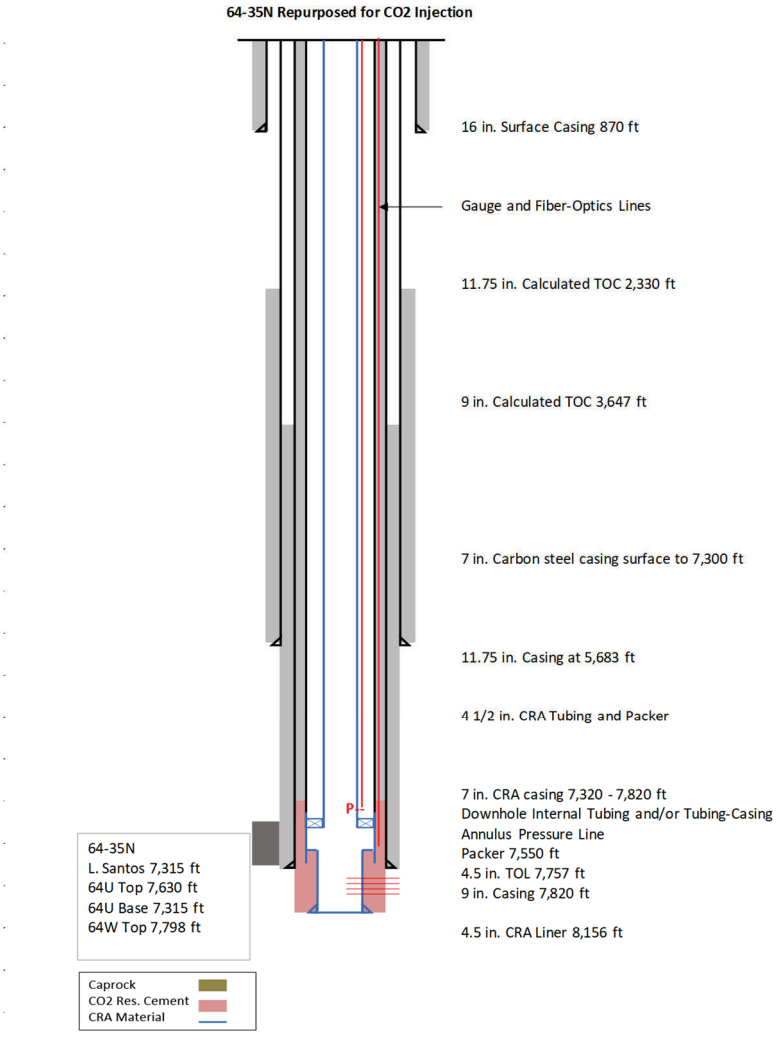

Figure 66: 64-35N Repurposed to CO_2 Injection Wellbore Schematic

6.6.1 Design Details and Assumptions

Table 54 shows the existing casing details with the un-cemented liner removed, the proposed inner casing, liner, and the proposed tubing design. The upper part of the table shows the existing casings and liner. The lower part of the table shows the proposed casing, liner, and tubing. The design depths for the casing, liner, and tubing are approximate and can be adjusted based on requirements for the final well construction and completion depths.

Table 54: 64-35N Casing, Liner, and Tubing

Notes:

(1) Proprietary connection indicates a connection with a metal-to-metal seal and strengths equivalent to the pipe body.

Directional Profile for 64-35N

The well was drilled as a vertical well.

Other Design Assumptions

The assumptions for the undisturbed temperature, pore pressure, fracture pressure, cement, and completion and packer fluid are the same as shown in Section 6.5.1.

6.6.2 64-35N Design Results

7 in. Inner Injection Casing

The design results and analyses for well 9-1N are valid for the 7 in. inner casing for this well. The 7 in. inner casing setting depths for both wells are very similar.

4 1/2 in. Tubing

The design results and analyses for well 9-1N are valid for the 4 1/2 in. tubing for this well. The 4 1/2 in. tubing setting depths for both wells are very similar.

4 1/2 in. Open Hole Liner

The design results and analyses for the new drill well are valid for the 4 1/2 in. liner for this well. The 4 1/2 in. liner setting depths for both wells are similar and the loads are the same.

6.7 Well 64-27N Repurposed Well Design

Well 64-27N has an un-cemented 4 3/4 in. liner and tieback casing that will be removed leaving open hole through the injection zone.

Figure 67 shows the 64-27N wellbore after conversion to a CO_2 injector. A new 6 5/8 in. inner casing with a section of CRA casing on bottom is proposed to isolate the existing 8 1/8 in. casing with the 6 5/8 in. inner casing set at the base of the Lower Santos confining layer. This design has a good chance of cementing the 6 5/8 in. casing to surface as required by the EPA and CARB because the low pressure injection zone can be temporarily isolated for running and cementing the 6 5/8 in. casing.

After the 6 5/8 in. inner casing is run and cemented, the open hole through the injection zone will be cleaned out and a 4 1/2 in. CRA liner can be run and cemented.

The completion includes a packer and CRA tubing to isolate the injected CO_2 from the casing. Monitoring equipment including fiber optic cable and downhole gauges are indicated.

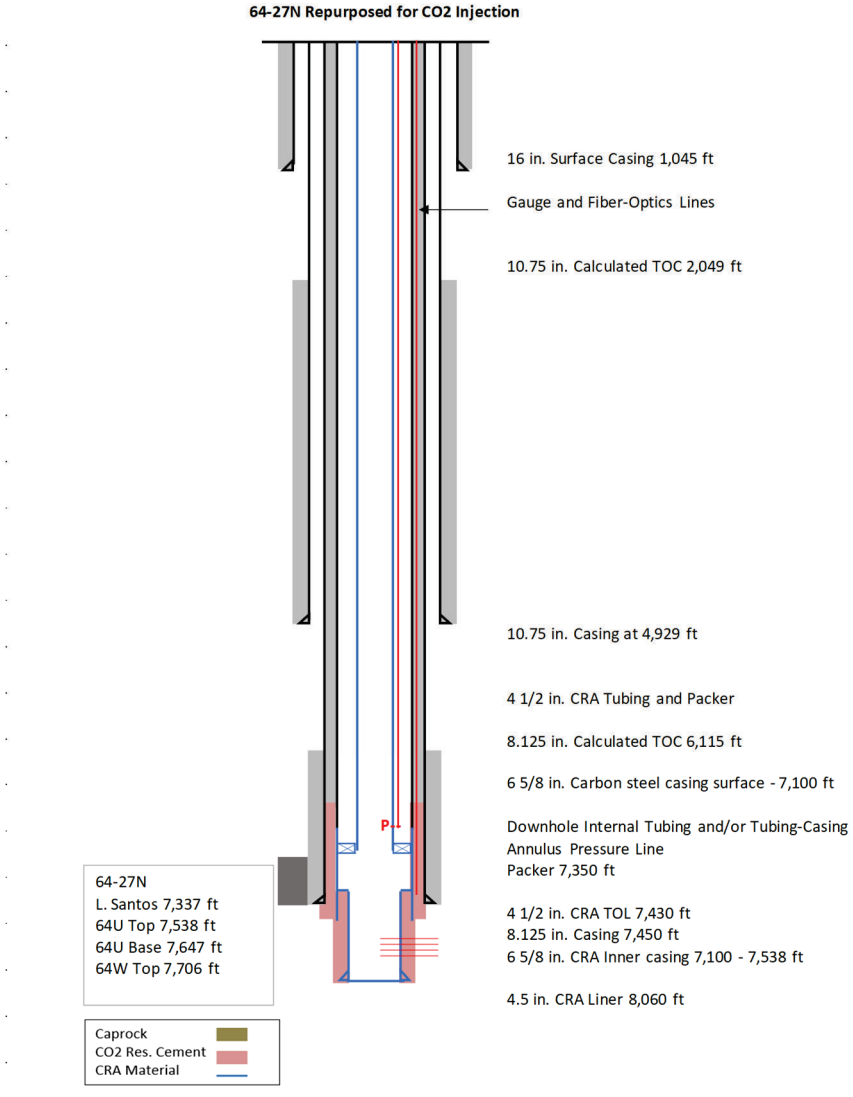

Figure 67: 64-27N Repurposed to CO_2 Injection Wellbore Schematic

6.7.1 Design Details and Assumptions

Table 55 shows the existing casing details with the un-cemented liner removed, the proposed inner casing, liner, and the proposed tubing design. The upper part of the table shows the existing casings and liner. The lower part of the table shows the proposed casing, liner, and tubing. The design depths for the casing, liner, and tubing are approximate and can be adjusted based on requirements for the final well construction and completion depths.

Notes:
(1) Proprietary connection indicates a connection with a metal-to-metal seal and strengths equivalent to the pipe body.

Directional Profile for 64-27N

The well was drilled as a vertical well.

Other Design Assumptions

The assumptions for the undisturbed temperature, pore pressure, fracture pressure, cement, and completion and packer fluid are the same as shown in Section 6.5.1.

6.7.2 64-27N Design Results

This section includes the results of the design analysis for the well. The analysis includes the 6 5/8 in. inner casing. A CRA material grade was evaluated for the lower section of casing and is recommended to meet the requirements for limiting corrosion during the life of the well. Refer to Section 5 for details on materials selection.

4 1/2 in. Tubing

The design results and analyses for well 9-1N are valid for the 4 1/2 in. tubing for this well. The 4 1/2 in. tubing setting depths for both wells are similar and the loads are the same.

4 1/2 in. Liner

The design results and analyses for the new drill well are valid for the 4 1/2 in. liner for this well. The 4 1/2 in. liner setting depths for both wells are similar and the loads are the same.

6 5/8 in. Inner Injection Casing with Nominal Wall

Table 56 shows the minimum safety factors for the 6 5/8 in. L80 Section 1 casing loads. The load number corresponds to the load number in Section 6.2. The safety factors assume nominal wall thickness with a tolerance of –12.5% resulting in remaining body wall (RBW) of 87.5%. The minimum safety factors all meet or exceed the design factors shown in Table 23.

Table 57 shows the minimum SFs for Section 2. The SFs meet the DFs.

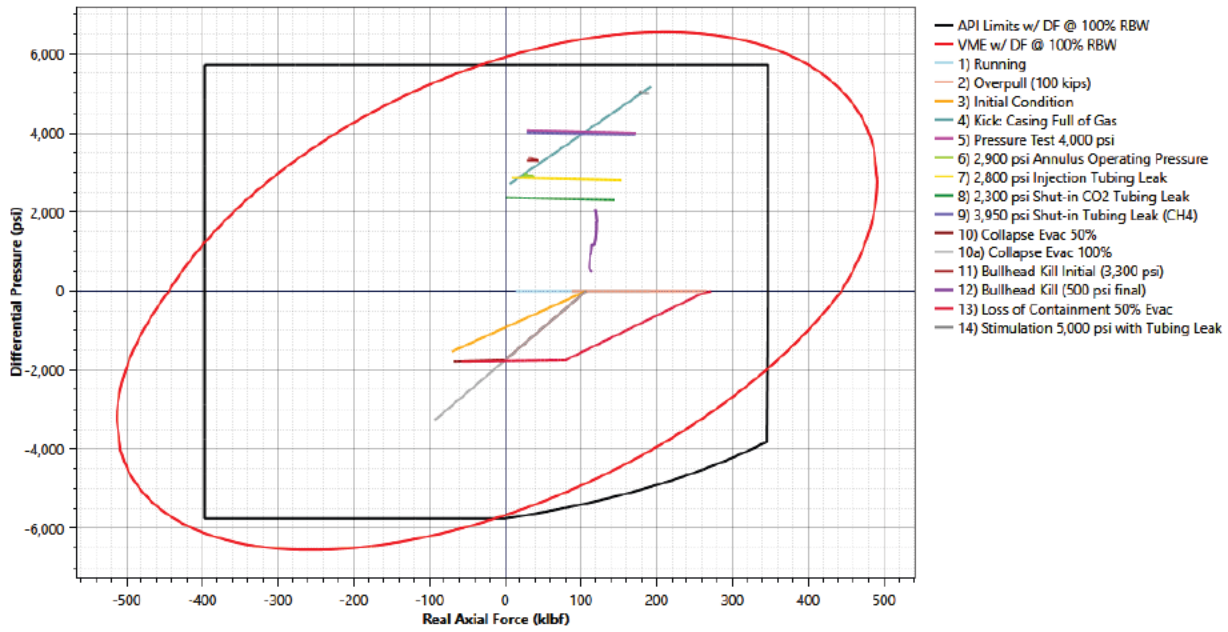

Figure 68: 6 5/8 in. Injection Casing with Nominal Wall Section 1 VME

Figure 69 shows the VME plot for the design loads.

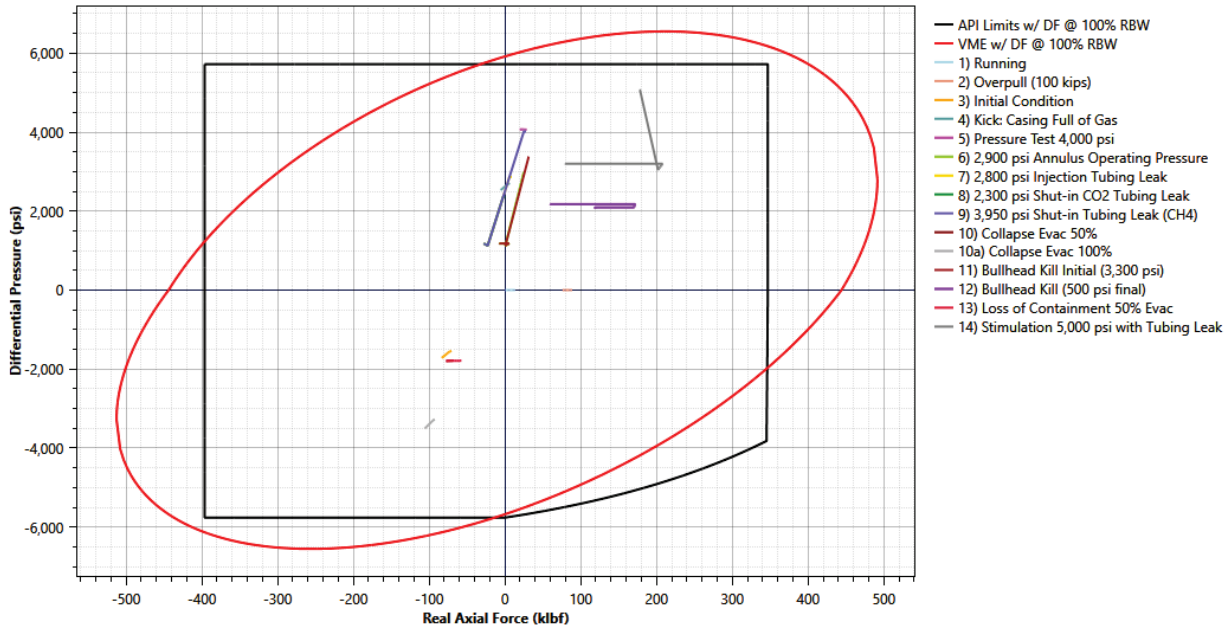

Figure 69: 6 5/8 in. Injection Casing with Nominal Wall Section 2 VME

6 5/8 in. Casing Wall with RBW 77.4% (25 years of service)

Table 59 shows the RBD results for information.

Table 58 shows the results for 77.4% RBW based on wall loss from Section 6.3. The SFs meet the DFs except for load "11) Collapse - Full Evacuation" and load "16) Stimulation 5,000 psi with Tubing Leak". The SFs in red font are less than the DF for the load design failure mode.

The collapse SF is less than the DF of 1.00. Full evacuation of the casing after 25 years of service is an unlikely load and can be considered a design check for information. The stimulation load is an early life load and is not planned for mid or late life. The results are shown for information.

Table 59 shows the RBD results for information.

6.8 Well 27R-27N Repurposed Well Design

Well 27R-27N will be cleaned out below the proposed injection perforations. Part of the existing 6 5/8 in. casing stub will be cut and removed.

Figure 73 shows the 27R-27N wellbore after conversion to a CO_2 injector. 7 in. injection casing will be run and cemented to surface in the 9 in. casing. A 4 1/2 in. CRA liner will be run and cemented.

The completion includes a packer and CRA tubing to isolate the injected CO_2 from the casing. Monitoring equipment including fiber optic cable and downhole gauges are indicated.

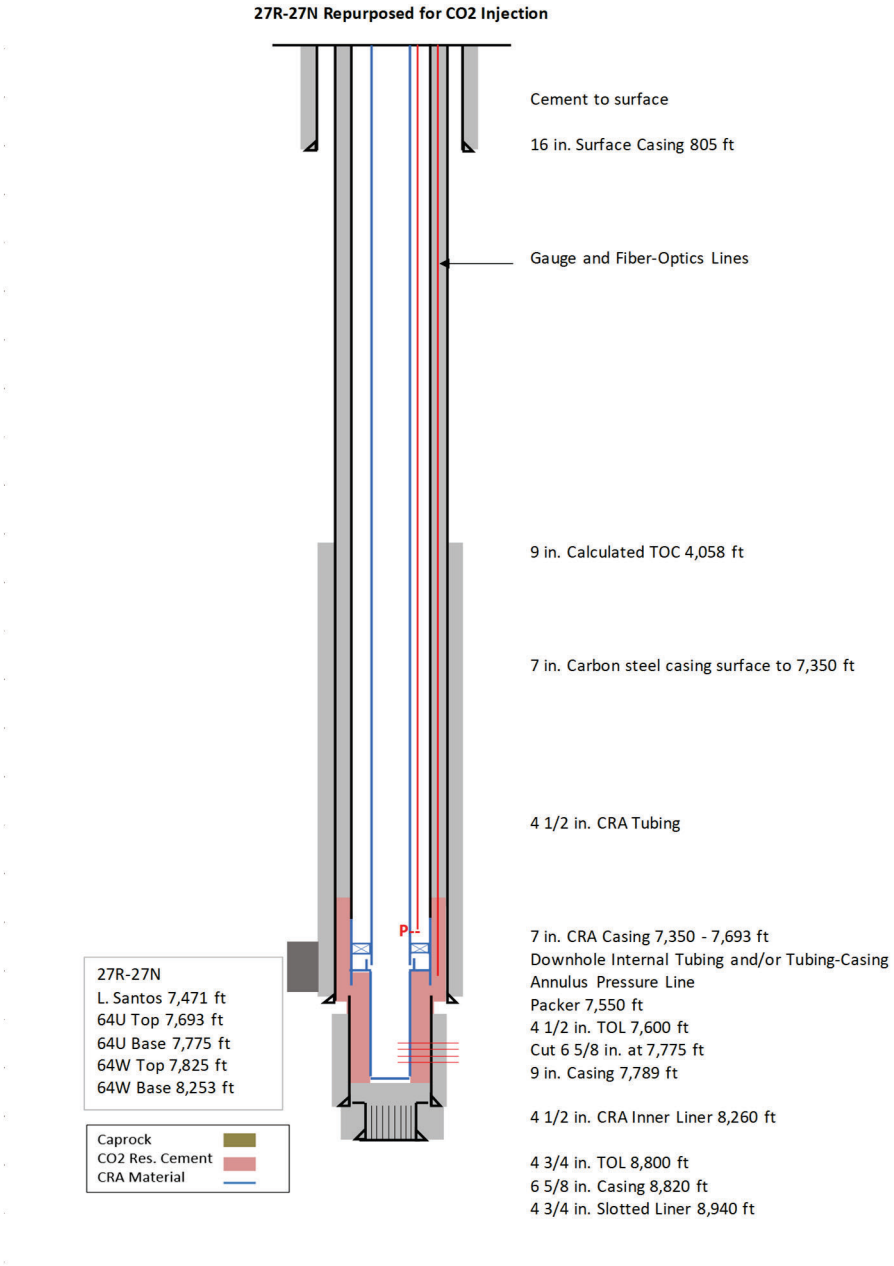

Figure 71: 27R-27N Repurposed to CO_2 Injection Wellbore Schematic

6.8.1 Design Details and Assumptions

Table 60 shows the existing casing details with the un-cemented liner removed, the proposed inner casing, liner, and the proposed tubing design. The upper part of the table shows the existing casings and liner. The lower part of the table shows the proposed casing, liner, and tubing. The design depths for the casing, liner, and tubing are approximate and can be adjusted based on requirements for the final well construction and completion depths.

Table 60: 27R-27N Casing, Liner, and Tubing

Notes:
(1) Proprietary connection indicates a connection with a metal-to-metal seal and strengths equivalent to the pipe body.

Directional Profile for 64-27N

The well was drilled as a vertical well.

Other Design Assumptions

The assumptions for the undisturbed temperature, pore pressure, fracture pressure, cement, and completion and packer fluid are the same as shown in Section 6.5.1.

6.8.2 27R-27N Design Results

7 in. Casing

The design results and analyses for well 9-1N are valid for the 7 in. inner casing for this well. The 7 in. inner casing setting depths for both wells are very similar.

4 1/2 in. Tubing

The design results and analyses for well 9-1N are valid for the 4 1/2 in. tubing for this well. The 4 1/2 in. tubing setting depths for both wells are similar and the loads are the same.

4 1/2 in. Liner

The design results and analyses for the 4 1/2 in. liner evaluated in Section 6.5 are valid for the 4 1/2 in. tubing for this well. The 4 1/2 in. liner setting depths for both wells are similar and the loads are the same.

6.9 Well 55-26N Repurposed Well Design

Well 55-26N will be cleaned out to below the proposed injection perforations.

Figure 72 shows the 55-26N wellbore after conversion to a CO_2 injector. 7 in. injection casing will be run and cemented to surface in the 9 in. casing.

The completion includes a packer and CRA tubing to isolate the injected CO_2 from the casing. Monitoring equipment including fiber optic cable and downhole gauges are indicated.

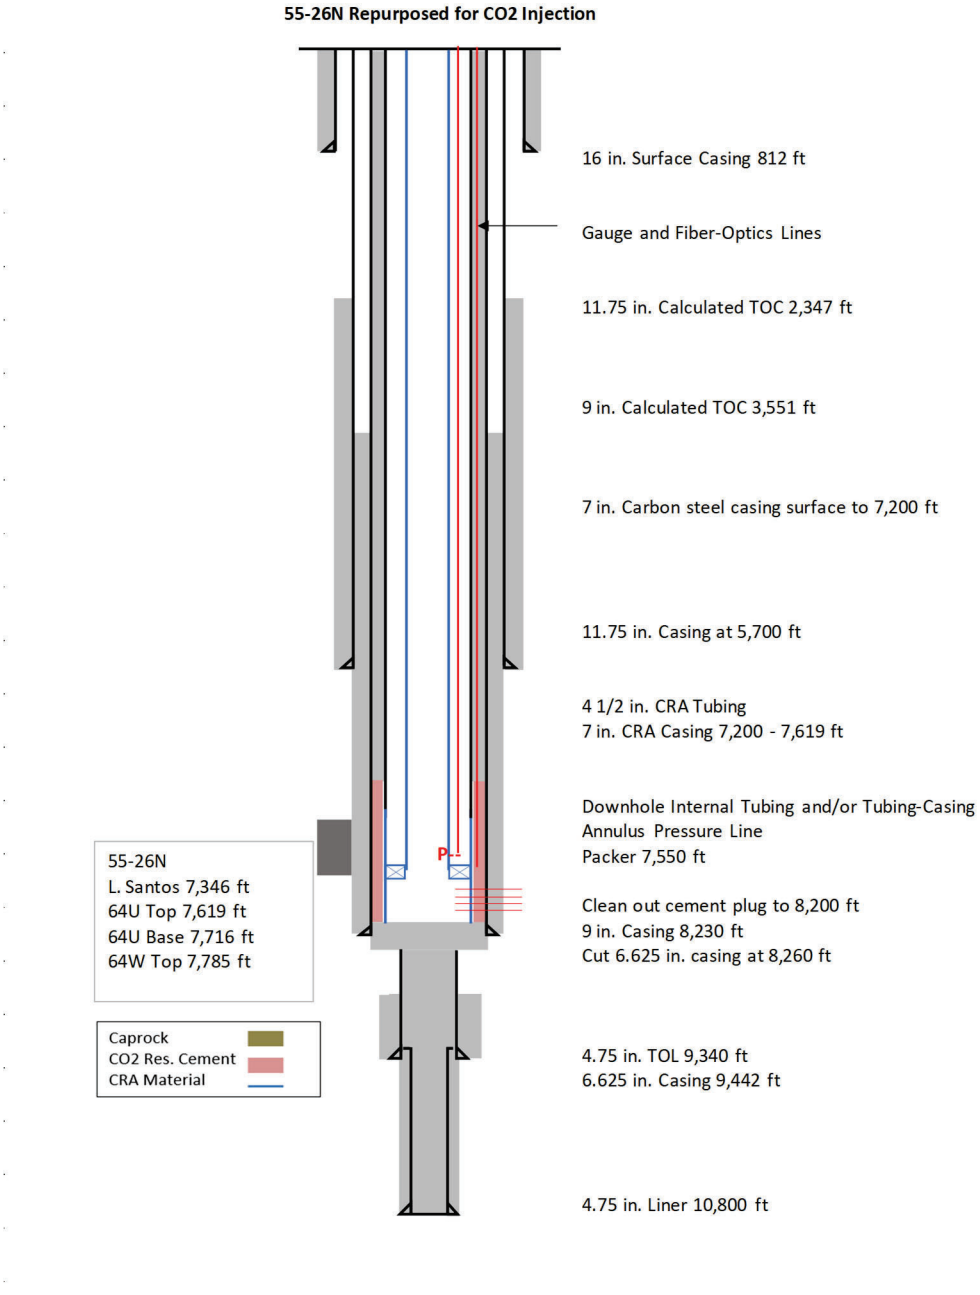

Figure 72: 55-26N Repurposed to CO_2 Injection Wellbore Schematic

6.9.1 Design Details and Assumptions

Table 61 shows the existing casing details with the un-cemented liner removed, the proposed inner casing, liner, and the proposed tubing design. The upper part of the table shows the existing casings and liner. The lower part of the table shows the proposed casing, liner, and tubing. The design depths for the casing, liner, and tubing are approximate and can be adjusted based on requirements for the final well construction and completion depths.

Table 61: 55-26N Casing, Liner, and Tubing

Sec	Name	Type	OD (in.)	Weight (ppf)	ID (in.)	WT (in.)	Grade	Conn.	Top MD (ft)	Bottom MD (ft)

Notes:
(1) Proprietary connection indicates a connection with a metal-to-metal seal and strengths equivalent to the pipe body.

Directional Profile for 64-27N

The well was drilled as a vertical well.

Other Design Assumptions

The assumptions for the undisturbed temperature, pore pressure, fracture pressure, cement, and completion and packer fluid are the same as shown in Section 6.5.1.

6.9.2 55-26N Design Results

7 in. Casing

The design results and analyses for the liner evaluated in Section 6.5 are valid for the 7 in. inner casing for this well. The 7 in. inner casing setting depths for both wells are very similar.

4 1/2 in. Tubing

The design results and analyses for well 9-1N are valid for the 4 1/2 in. tubing for this well. The 4 1/2 in. tubing setting depths for both wells are similar and the loads are the same.

6.10 New Drill Injection Well Design

A new drill injection well design was conducted as part of the study. The well design is to run and cement 7 in. injection casing above the injection zone, set a 4 1/2 in. liner through the injection zone, and complete with 4 1/2 in. tubing.

Figure 73 shows the proposed well design. 7 in. injection casing with a section of CRA casing on bottom is proposed. This design improves the chances of cementing the 7 in. casing to surface as required by the EPA and CARB.

After the 7 in. injection casing is run and cemented, the injection zone will be drilled and a 4 1/2 in. CRA liner will be run and cemented.

The completion includes a packer and CRA tubing to isolate the injected CO_2 from the casing. Monitoring equipment including distributed temperature sensing (DTS) and downhole gauges are indicated in the figure.

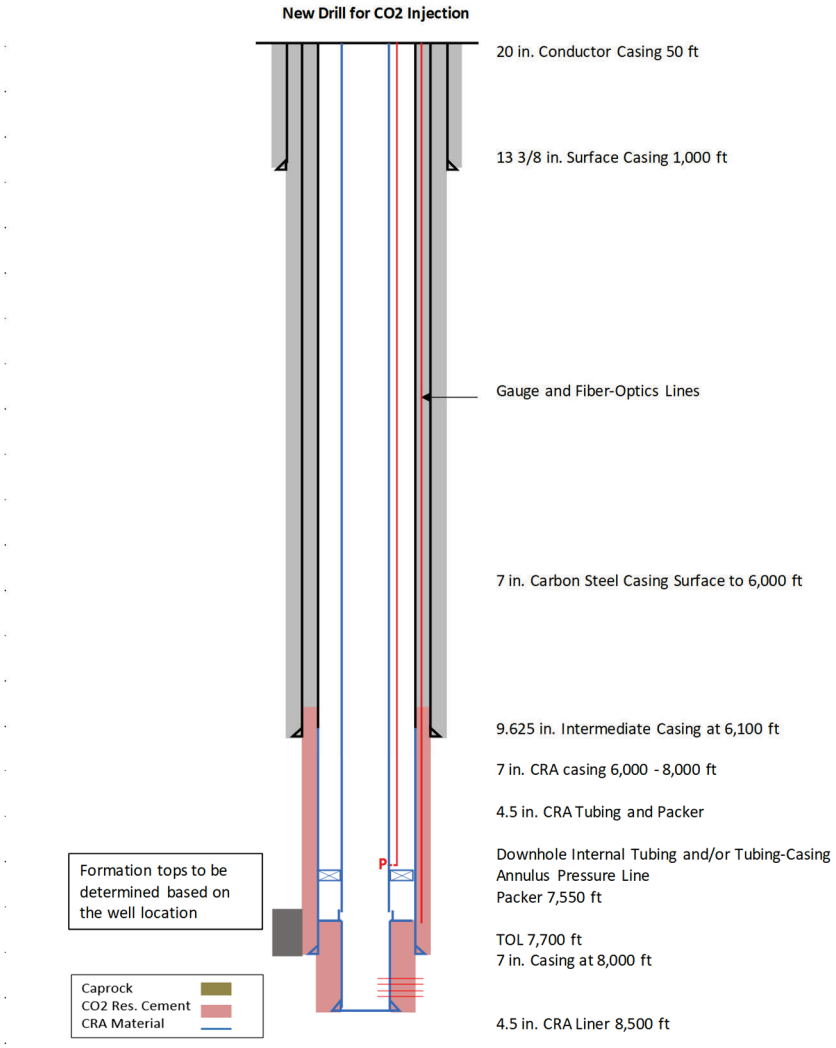

Figure 73: New Drill CO_2 Injection Wellbore Schematic

6.10.1 Design Details and Assumptions

Table 62 shows the new drill well design with the proposed upper casing strings, injection casing, liner, and the proposed tubing. The design depths for the casings, liner, and tubing are approximate and can be adjusted based on requirements for the final well construction and completion depths.

Table 62: New Drill Casing, Liner, and Tubing

Sec	Name	Type	OD (in.)	Weight (ppf)	ID (in.)	WT (in.)	Grade	Conn.	Top MD (ft)	Bottom MD (ft)

1	Injection	Tubing	4 1/2	11.6	4.000	0.250	Mod 13Cr80	Proprietary (1)	0	7,700

Notes:

(1) Proprietary connection indicates a connection with a metal-to-metal seal and strengths equivalent to the pipe body.

Directional Profile for New Drill Wells

The wells will be drilled as vertical wells.

Other Design Assumptions

The assumptions for the undisturbed temperature, pore pressure, fracture pressure, cement, and completion and packer fluid are the same as shown in Section 6.5.1.

6.10.2 New Drill Well Design Results

This section includes the design results for the new drill well design with 7 in. casing set at the base of the Lower Santos shale, a 4 1/2 in. liner set through the injection zone with a 4 1/2 in. tubing and packer completion.

13 3/8 in. Surface Casing

Table 63 shows the design results for the 13 3/8 in. surface casing. The SFs meet or exceed the DFs.

Table 63: Minimum Safety Factors for the 13 3/8 in. Surface Casing

	Burst		Collapse		Tension		Compression		Triaxial	
Load Case	SF	MD (ft)	SF	MD (ft)	SF	MD (ft)	SF	MD (ft)	SF	MD (ft)

5. Burst: Pressure Test to 1,000 psi	1.45	5,296	--	--	>3	0	>3	6,100	1.56	5,296
6. 50% Evacuation	--	--	1.60	6,100	>3	0	>3	6,100	2.43	3,050

4 1/2 in. Tubing

The design results and analyses for well 9-1N are valid for the 4 1/2 in. tubing for the new drill wells. The 4 1/2 in. tubing setting depths for the wells are similar.

7 in. Casing with Nominal Wall

Table 65 shows the minimum safety factors for the 7 in. 26 ppf L80 casing Section 1 loads. The load number corresponds to the load number in Section 6.2. The safety factors assume nominal wall thickness with a tolerance of –12.5% resulting in remaining body wall (RBW) of 87.5%. All load SFs meet the DFs for Section 1.

Table 66 shows the minimum safety factors for Section 2 of the casing. All DFs are meet or exceed the design factors shown in Table 23.

Table 65: Minimum Safety Factors for the 7 in. 26 ppf L80 Section 1 Injection Casing with Nominal Wall

6.11 API RP 90-2 MAWOP Analysis

As discussed in Section 6.1.3, when wells are operated with annulus pressure, a MAWOP can be calculated according to RP 90-2 requirements.

6.11.1 7 in. Casing x 4 1/2 in. Liner x 4 1/2 in. Tubing Well Design

Wells can be operated safely with sustained annulus pressure. API Recommended Practice 90-2 [20], Annular Casing Pressure Management for Onshore Wells provides recommendations for operating wells with annulus pressure. The recommended practice document defines the maximum allowable wellhead operating pressure (MAWOP) for an annulus.

The proposed maximum annulus pressure is 2,900 psi based on the tubing injection pressure of 2,800 psi. Table 71 shows the allowable annulus pressure based on the derating criteria of the casing and tubing using the simple derating method defined in RP 90-1. The maximum allowable wellhead pressure (MAWOP) is the minimum of the allowable annulus pressures. The MAWOP is 3,160 psi compared to the proposed annulus pressure of 2,900 psi. Therefore, the design meets the RP 90-2 requirements.

Table 71: API RP 90-1 Allowable Annulus Pressure

RP 90-1 Derating Criteria	Tubular	API Burst or Collapse (psi)	Allowable Annulus Pressure (psi)
75% of inner tubular collapse rating	4 1/2 in. 11.6 ppf 13Cr80	6,350	4,763
50% of outer tubular burst rating	7 in. 26 ppf L80	7,240	3,620
80% of next outer tubular burst rating	9 5/8 in. 40 ppf K55	3,950	3,160

6.12 Cementing Comments and Recommendations

The following are general comments and recommendations regarding cementing the casing and liners in the various well types. Cementing to surface the surface casing and injection long string casing is a regulatory requirement. Cementing the intermediate casing to surface has the advantage of simplifying the future abandonment.

A well design with a liner set through the injection zone and a long string casing set above the injection zone has an advantage of less differential pressure across the depleted 64 Zone Sands, helping to ensure good mud displacement by the cement and resulting in a well design with cement circulated to surface as required.

6.12.1 Surface Casing Cementing

Cemented with a light-weight lead and tail slurries. Top of cement at surface.

Lead Slurry: 12.5 ppg extended Class G + (lost circulation material) LCM and fluid loss additives

Tail Slurry: 13.5 ppg extended Class G + LCM and fluid loss additives

General slurry comments: The need for accelerators or retarders will be determined during pilot testing. Choice of extender and mix water ratio must consider the minimization of free water. Centralize casing to provide 70% stand-off.

Cementing pressure calculations indicate that the pressure profile remains above the pore pressure, but the fracture pressure will be exceeded by approximately 120 psi during displacement.

Pump 50 – 100% excess slurry volume to ensure cement is circulated to surface. Excess will depend on hole conditions specific to the well.

Plan for a top job in the event the cement top drops after displacement.

6.12.2 Intermediate Casing Cementing

Cemented in two stages with the stage collar at 2,000 ft.

The first (bottom) stage will be cemented with a light-weight lead slurry and standard weight tail slurry.

The second (upper) stage will be cemented with a light-weight slurry. Top of cement at surface.

Stage 1 Lead Slurry: 12.5 ppg extended Class G + lost circulation material (LCM) and fluid loss additives.

Stage 1 Tail Slurry: 15.8 ppg Class G cement system + LCM and fluid loss additives.

Stage 2 Slurry: 12.5 ppg extended Class G + LCM and fluid loss additives.

General slurry comments: The need for accelerators or retarders will be determined during pilot testing. Choice of extender and mix water ratio must consider the minimization of free water. The casing will be centralized to provide 70% stand-off.

Cementing pressure calculations indicate that the pressure profile remains within the pore and fracture pressure window, for the first stage. The fracture gradient is exceeded by approximately 200 psi during the second stage.

Pump 25% excess slurry volume for the first stage.

Pump 50 – 100% excess slurry volume for the second stage to ensure cement is circulated to surface. Excess volume will be determined based on hole conditions while drilling specific to the well.

A top job should be planned in the event the cement top drops after displacement.

6.12.3 Injection Casing Cementing

Cemented with a light-weight lead slurry and standard weight tail slurry. Top of cement at surface.

Lead Slurry: 12.5 ppg extended Class G + LCM and fluid loss additives

Tail Slurry: 15.8 ppg CO_2-Resistant cement system + LCM and fluid loss additives

General slurry comments: The need for accelerators or retarders will be determined as part of the slurry design and during pilot testing. Choice of the extender and mix water ratio will be considered to minimize free water. The casing will be centralized to provide 70% stand-off.

CO_2-Resistant cement systems considered for the tail slurry include densified 50:50 Fly-Ash and Portland cement, Portland cement with Latex, and proprietary CO_2-Resistant blends.

Densified 50:50 Fly-Ash and Portland cement is recommended for the following reasons:

- The reactive Portland cement content is reduced by 50%
- Exposure to CO_2 is limited to the annular cross-section at the casing shoe (vertical attack) under static conditions
- Cost effective for large slurry volumes

Cementing pressure calculations indicate that the pressure profile remains within the pore and fracture pressure window, providing the depleted zone is not penetrated during drilling.

Pump 25% excess slurry volume to ensure cement is circulated to surface for new drill wells.

Pump 10 – 15% excess slurry volume to ensure cement is circulated to surface for pipe-in-pipe repurposed wells.

Confirm that the open hole formation integrity is sufficient to support the cement job pressures before casing is run. An open-hole bottom plug may be required to isolate the low pressure injection zone.

6.12.4 Injection Liner Cementing

No lead slurry. Tail (single) slurry cemented to the top of the liner.

Slurry: Light-weight CO_2-Resistant cement system

General slurry comments:

Managed Pressure Cementing (MPC) with foamed water pumped ahead of the slurry to reduce the amount of differential pressure across the depleted 64 Zone sands will be considered based on the specific actual well conditions. UIC Program Director approval for using MPC will be requested.

The liner will be centralized to provide 70% stand-off.

CO_2-Resistant cement systems considered include proprietary CO_2-Resistant blends, calcium aluminate cement (CAC), and resin cements.

Resin cement is recommended for the following reasons:

- No reactive species present (very high CO_2 resistance).

- More ductile than conventional cements, making it more durable under cyclic loading conditions.
- Can be mixed as light as 9.0 ppg, making a good candidate for cementing the depleted 64 Zone Sands.

Cementing pressure calculations indicate that the cement pressure profile is far above the pore pressure profile except for the open hole above the depleted zone. The high differential pressure suggests that fluid losses to the depleted zone with conventional cement slurries is likely.

The recommended excess volume is 25% for a liner cement job in open hole based on the caliper log.

The recommended excess volume is 10 – 15% for a liner cement job pipe-in-pipe.

A liner top packer should be run to ensure liner lap isolation.

6.13 Casing and Tubing Connections

6.13.1 Repurposed Wells

The recommended connections for the new injection inner casing, liners, tubing, and completion equipment are connections with metal-to-metal seals and full pipe body strength. The design results in this report assume full pipe body strength for the connections. If there is a need to use connections with reduced OD because of clearance requirements, it is recommended to evaluate the connection tensile and compression strengths and the load requirements on a case by case basis.

6.13.2 New Drill Wells

API connections are acceptable for the surface and intermediate casing for the new drill wells.

The recommended connections for the new injection casing, liners, tubing, and completion equipment are connections with metal-to-metal seals and full pipe body strength. The design results in this report assume full pipe body strength for the connections.

6.14 Annular Pressure Management

The A annulus (tubing × injection casing) is subject to pressure changes including maintaining the annulus pressure higher than the tubing surface injection pressure and temperature changes of the annulus fluid caused by injection and shut-in cycles. Maintaining the annulus pressure above the injection is a Class VI requirement. The EPA also requires monitoring and reporting the volume of annulus fluid added.

An annulus pressure management (APM) system is recommended to maintain the correct annulus pressure within a prescribed range to meet the well operating requirements. The APM needs to be designed to add fluid and increase the pressure as the injection pressure rises and to bleed off pressure when the annulus pressure exceeds the upper limit of pressure range. A liquid fluid system is implied to track the volume of fluid added to the annulus as required for Class VI wells. The fluid used to manage the pressure needs to be inert, free of oxygen, and stable for long term maintenance free use. The APM needs a pressure relief system as backup to relieve any excess pressure. The reservoir for the fluid needs to be sized to handle the maximum volume of fluid required to maintain the pressure with excess capacity and a way to measure the volume added. A closed system for the annulus fluid is required to maintain an oxygen free fluid.

When the well is started up the BHP and injection pressure will be low. The APM needs to be designed so that the annulus pressure tracks the injection pressure plus a pressure of approximately 100 psi to meet Class VI requirements. As injection continues, the annulus fluid will heat up and the APM system will bleed fluid to compensate for increasing annulus pressure. If the well is shut-in, the annulus fluid will cool and the pressure will decrease.

Over pressuring the annulus can cause the casing to fail in burst or the tubing to fail in collapse. The APB (annular pressure buildup) for an injection well where the annulus fluid is heated because of injection has been modeled.

Table 72 shows the APB results for the well design with 7 in. casing and 4 1/2 in. tubing. As shown in the table, the change in pressure per unit temperature change is significant. The APB of approximately 4,100 psi for a trapped annulus can be above the burst and collapse strength of the casing and tubing, respectively, so a properly designed and reliable APM system is a requirement. The APB is the additional pressure buildup because of fluid thermal expansion in addition to the original annulus pressure which can be as high as 2,900 psi for the operating annulus pressure for an injection well. The change in volume for the case modeled is approximately 3 bbl.

Table 72: Modeled Injection Well APB Results for the 7 in. × 4 1/2 in. Well Design

Annulus	APB ΔP	Volumetric ΔT	ΔVolume	Ann. ΔVolume	ΔP/ΔT
A (tubing × casing)	4,145 psi	41.7°F	2.5 bbl	2.5 bbl	99.4 psi/°F

7 Nomenclature

7.1 Abbreviations and Acronyms

Term	Definition
APB	Annular Pressure Buildup
APM	Annular Pressure Management
CAC	Calcium aluminate cement
CH_4	Methane
CO_2	Carbon dioxide
CRA	Corrosion Resistant Alloy
DTS	Distributed Temperature Sensing
EOS	Equation of State
EPDM	Ethylene propylene diene monomer
FEED	Front End Engineering and Design
GF	Glass Filled
h	Formation layer thickness
HNBR	Hydrogenated Nitrile Butadiene Rubber
ID	Inside diameter
IPR	Inflow performance relationship
k	Formation Permeability
krg	Formation permeability relative to gas
LCM	Lost circulation material
LTC	Long Thread and Coupled
MAWOP	Maximum Allowable Wellhead Operating Pressure
mpy	Mills per year (0.001 in. per year)
mtpa	Million (metric) tons per annum
N_2	Nitrogen
OD	Outside diameter
P&A	Plug and Abandon
PBR	Polished Bore Receptacle
PEEK	Polyetheretherketone
POE	Probability of Exceedance
POF	Probability of Failure
ppf	Pounds per foot
PTFE	Polytetrafluoroethylene
PVT	Pressure-Volume-Temperature
RBD	Reliability Based Design

Term	Definition
RBW	Remaining Body Wall
RGD	Rapid Gas Decompression
SCSSV	Surface Controlled Subsurface Safety Valve
SITP	Shut In Tubing Pressure
VLP	Vertical Lift Profile
WSD	Working Stress Design

9.3 Effect of NH_3 in pH and Corrosion of Carbon Steel and 13Cr

Figure 79 shows the pH of the liquid water (aqueous) phase forming from the injection stream with and without NH_3. The plot indicates that the electrolyte becomes acidic in the absence of NH_3.

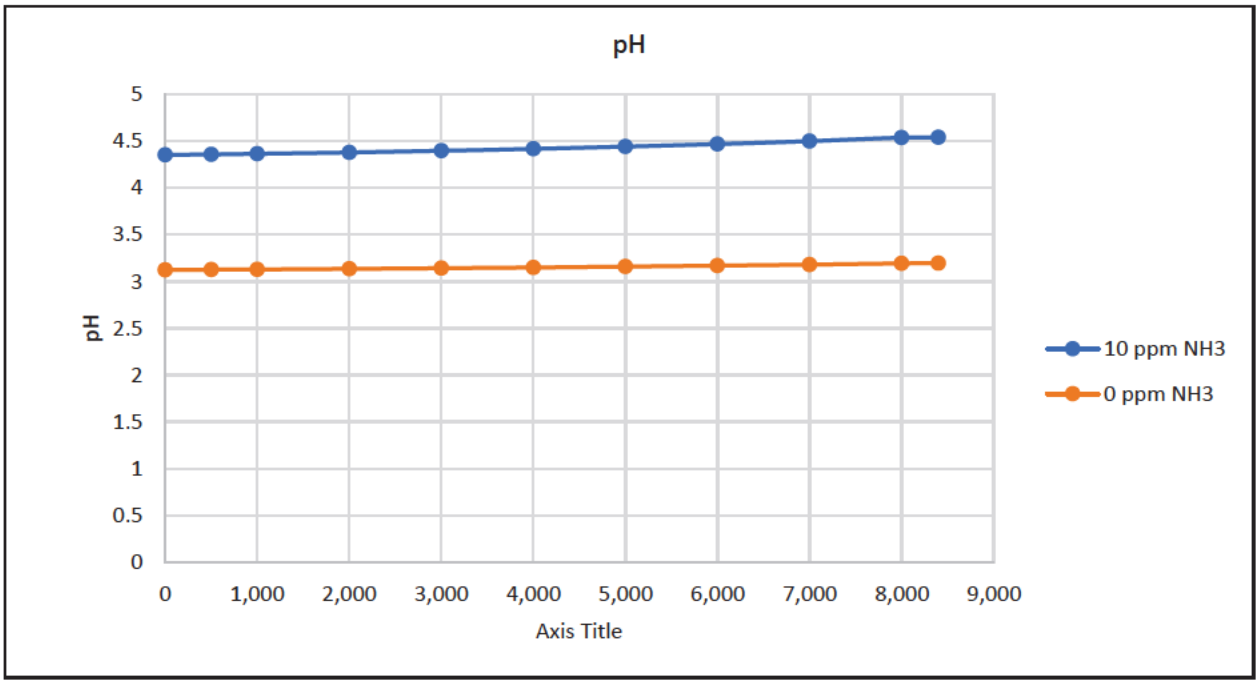

Figure 79: Effect of NH_3 in pH of the Pre-Combustion Stream

Figure 80 and Figure 81 shows the effect of NH_3 in the corrosion rates of carbon steel and 13Cr respectively. The corrosion of these materials increases in the absence of NH_3.

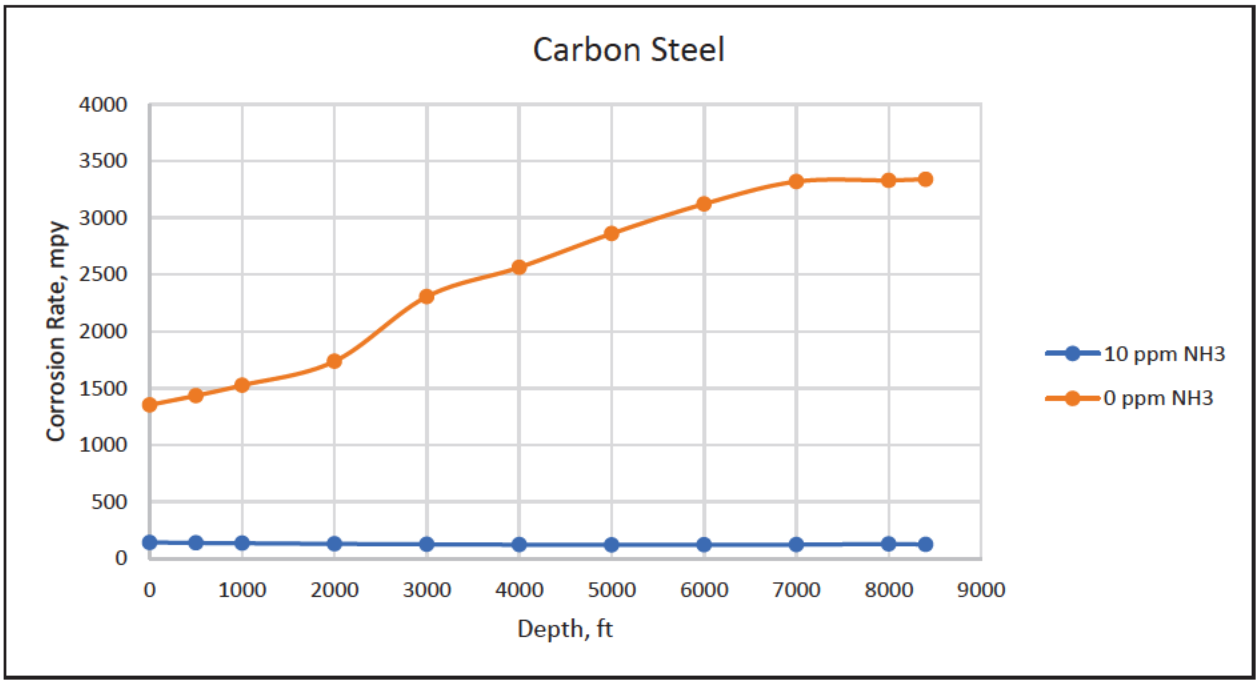

Figure 80: Effect of NH_3 in the Corrosion of Carbon Steel

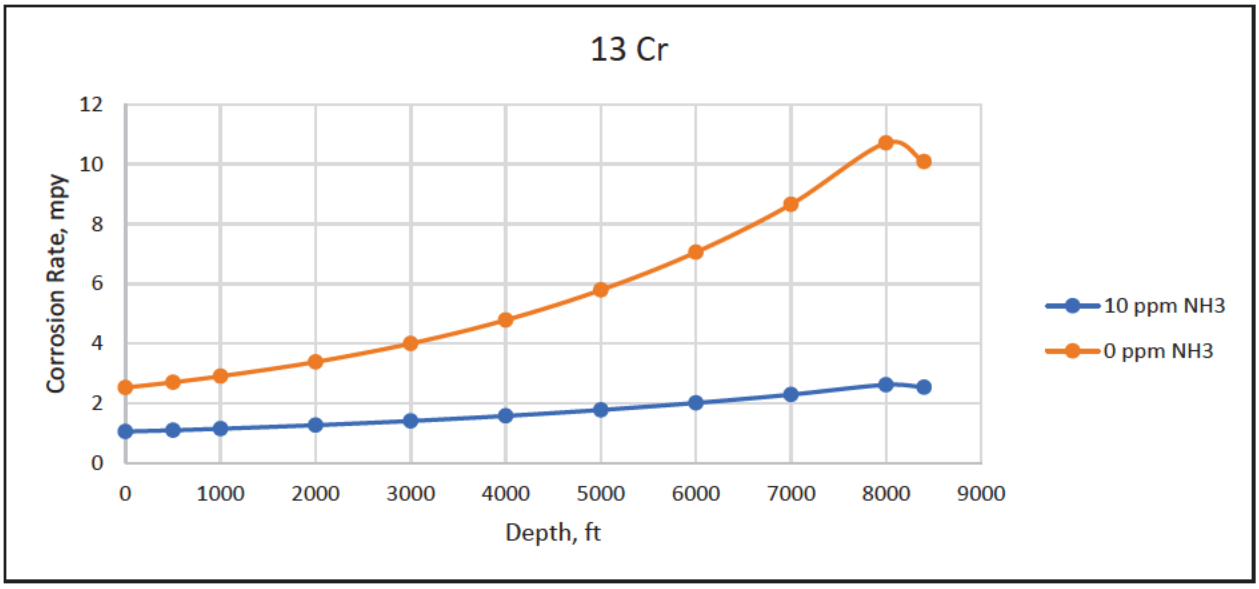

Figure 81: Effect of NH_3 in the Corrosion of 13Cr

10 Appendix B—Reliability Based Design Overview

Consideration of uncertainty is imperative in all design approaches. In traditional WSD, the uncertainty in load and strength is addressed using elastic strength estimates based on minimum properties, only within its elastic limit. This design method has been used widely and successfully by the oil and gas industry for decades.

WSD relies on the demonstration of design adequacy through satisfaction of prescribed design factors, such that only an allowable fraction of minimum strength is used in design. One limitation of the approach is the lack of insight into the implications of not satisfying these prescribed safety factors.

RBD methods have been in use for decades in the design of load-bearing structures. In RBD, it is explicitly recognized that strength and load are stochastic (i.e., of random distribution) in nature because they depend upon parameters that exhibit uncertainty and variability. For example, for tubulars, strength is based on parameters such as diameter, wall thickness, yield strength, and ultimate tensile strength. It is well recognized that because of the manufacturing and measurement processes involved, there is uncertainty in these parameters. For this reason, manufacturing specifications set allowable limits and ranges on many of these parameters. Likewise, load parameters also have uncertainty and variability associated with them. For example, in well design, parameters that define loads, such as pore pressure, fracture pressure, and temperature are uncertain and cause variability in the magnitude of the load. Further, a given load considered in design may not occur at all and yet introduces uncertainty associated with the probability of occurrence of the load itself.

In RBD, strength and load are treated as random variables with known or measurable statistical distributions (probability density functions). Load effect distribution is more difficult to characterize because the required data are not always readily available, and RBD often requires the application of extreme value statistics. For this reason, the extreme event may be absent from available load data sets. In the most general applications of probabilistic design, both the load and the tubular ratings are treated as random variables. These probability distributions are developed based on rigorous statistical analysis of field load histories and actual test results on tubular performance. Reliability methods are then used to combine these distributions and quantify the *probability* that the load will exceed the strength under specified conditions. This is the P_f, and its magnitude quantitatively conveys the risk of failure. In design, the maximum P_f calculated should be less than a *target probability of failure*.

In practice, it is often difficult and cumbersome to obtain load data and rigorously quantify load side distributions. Moreover, designers often seek to understand whether a given tubular can withstand a given load at a *prescribed* magnitude. This is best answered by using a subset of RBD, known as *Level-4 RBD*. In Level-4 RBD, the load is deterministic at a prescribed (usually extreme) magnitude, and the strength is probabilistic, with distributions constructed from the statistical data on strength parameters (Figure 82). The failure probability, that is, the probability that the deterministic load exceeds the stochastic strength, is given by the yellow-shaded area under the strength probability density function to the left of the load distribution, which is a vertical line (it is deterministic). This is the P_f if the load under consideration occurs at the assumed magnitude for the given tubular.

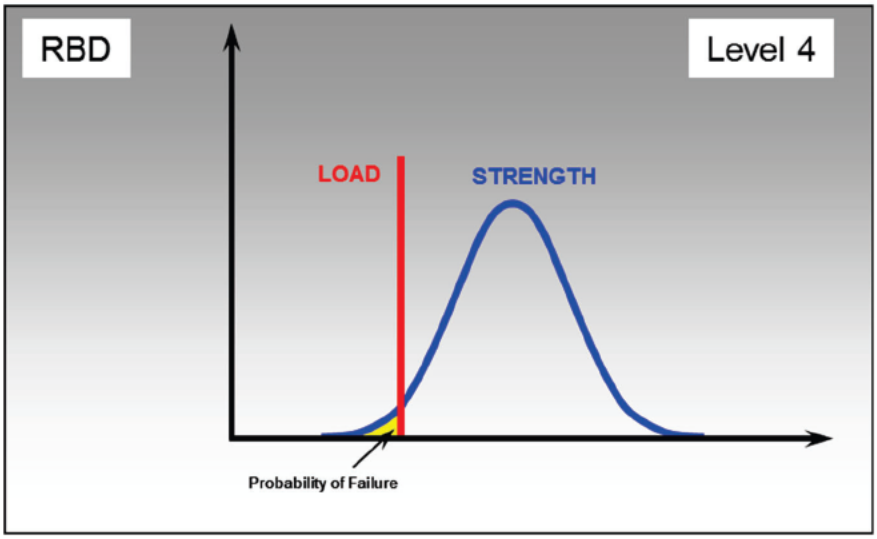

Figure 82: Level-4 Reliability-Based Design Analysis

Level-4 RBD is used to determine if the casing is likely to fail for a given load condition. The Klever-Stewart tension-burst limit state, as described in API Technical Report 5C3 [21], is used as the limit state strength. Strength uncertainty is characterized by using statistical data on strength-defining parameters. The P_f is calculated based on the Klever-Stewart tension-burst limit state. Also, the Probability of Exceedance (POE) is calculated as the probability that the VME stress will exceed the yield strength of the casing. Although this does not necessarily imply failure, it is an important indicator of impending failure and is sometimes of interest in design situations where yielding is not acceptable. The POE is also indicative of the probability of connection leaks because connection performance is usually referenced to the pipe body yield envelope. Design criteria for Level-4 RBD analysis are shown in Table 76.

Table 76: Level-4 RBD Design Criteria

Failure Mode and Load Type	Minimum Design Criterion
Probability of Exceedance (VME)	
Service Loads	$\leq 10^{-4}$
Survival Loads	$\leq 10^{-3}$
Probability of Failure (Burst-Tension)	
Service Loads	$\leq 10^{-6}$
Survival Loads	$\leq 10^{-5}$
Probability of Failure (Collapse)	
Service Loads	$\leq 10^{-3}$
Survival Loads	$\leq 10^{-2}$

Here, probability of failure (POF) is the probability of the load exceeding the limit state strength and probability of exceedance (POE) is the probability of exceeding the VME criterion, i.e., the probability the casing will yield (but not fail).

11 Appendix C—Undisturbed Temperature Profile

Table 77 shows the undisturbed geothermal temperature profile assumed for the analysis. Figure 83 shows the geothermal temperature vs. TVD.

Table 77: Undisturbed Geothermal Temperature Data

No.	TVD (ft)	Temperature (°F)	Gradient (°F/ft)

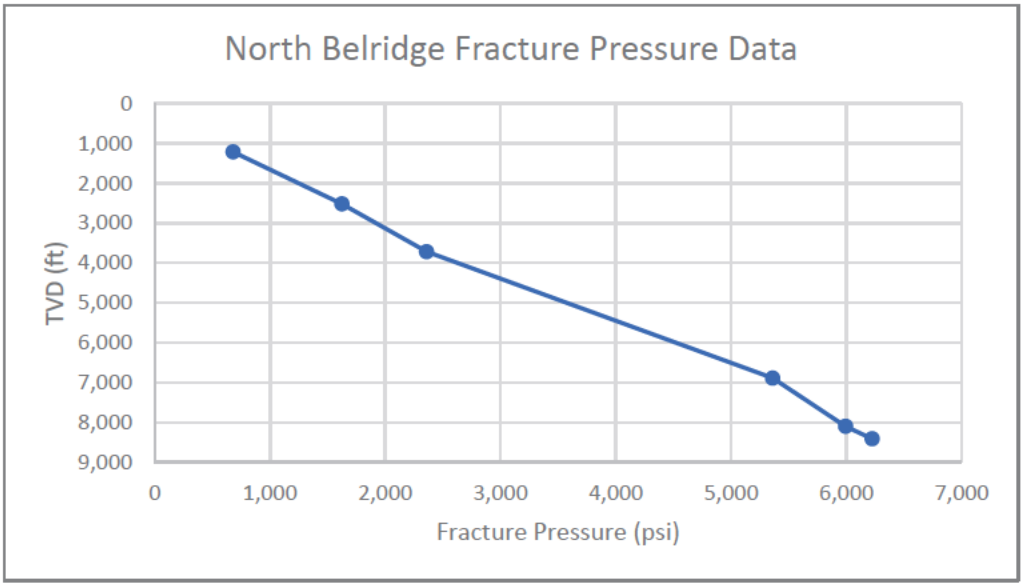

Figure 85: Estimated Fracture Pressure vs. TVD

13 Appendix E—Cementing Design Assumptions

Cement density and pressure affect the casing initial condition. Table 80 shows the lead and tail slurry densities that will be used in the casing design evaluations. A low cement density for the liner will be assumed because of the expected low BHP. Similar to drilling fluid density, cement density and top of cement have a minor impact on the final loads and stresses.

Table 80: Cement Density

Hole Section	Lead Cement (ppg)	Tail (ppg) (height)	TOC
Surface Casing	12.5	13.5 (300 ft)	Surface
Intermediate Casing	12.5	15.8 (300 ft)	Surface
Injection Casing	12.5	15.8 (500 ft)	Surface
Injection Liner	N/A	12.5	Top of liner

14 Appendix F—Design Analysis Results for 9 in. Casing

The repurposed well's 9 in. production casing was evaluated for injection well design loads to see if it is feasible to consider using the existing 9 in. casing for the injection casing. The 9 in. casing in well 64-35N was evaluated using the design loads as documented in the DPD Version 4.

The conclusion is that the even if the 9 in. casing is inspected and is found to have nominal wall thickness, the burst strength of the 9 in. casing is not sufficient to meet the load requirements. Therefore, it is recommended to isolate the 9 in. casing with inner casing cemented to surface for a well design that meets the requirements for Class IV wells.

The analysis results for 9 in. casing also applies to wells with other size casing such as 8 1/8 in. OD with similar burst strengths.

14.1 9 in. Casing with Nominal Wall Design Results

Table 81 shows the minimum safety factors for the 9 in. 45 and 46.1 ppf J55 casing loads. The load number corresponds to the load number in Section 6.2. The safety factors assume nominal wall thickness with a tolerance of –12.5% resulting in remaining body wall (RBW) of 87.5%. Most of the minimum burst and triaxial safety factors do not meet the design factors shown in Table 23 with nominal wall. If it is found that the actual remaining wall is less than 87.5% the safety factors will be further reduced. Therefore, it is not recommended to consider the 9 in. casing as the secondary barrier for CO_2 injection wells.

RBD methodology was developed and calibrated based on modern API specifications and casing manufacturing data. While RBD analysis is not valid for this non-API casing, Table 82 shows the RBD results for the load analysis. Some of the critical design loads including "5) Pressure Test 4000 psi" and "10) Tubing Leak with 3650 psi SITP with CH4" do not meet the acceptance criteria for RBD as shown in Table 25.

Table 81: Minimum Safety Factors for the 9 in. J55 Casing with Nominal Wall with Injection Well Loads
