CarbonFrontier

CLASS VI PERMIT

APPLICATION NARRATIVE

40 CFR 146.82(a)

PLAN VERSION NUMBER: 5

PLAN DATE: October 2024

AERA

Aera Energy LLC and Geosyntec Consultants, Inc., with technical support from SLB, Blade Energy Partners, and Netherland, Sewell & Associates, prepared the documents that comprise the Class VI Permit Application

Geosyntec consultants

CLASS VI PERMIT APPLICATION
NARRATIVE 40 CFR 146.82(a)
CarbonFrontier Project

TABLE OF CONTENTS

1. PROJECT BACKGROUND AND CONTACT INFORMATION 1
1.1 Project Summary/Background 1
1.2 Carbon Dioxide Capture Method 3
1.2.1 Pre-Combustion Capture: Process Description Summary 3
1.2.2 Post-Combustion Capture: Process Description Summary 3
1.2.3 Imported CO2: Process Description Summary 3
1.3 Contact Information 4
1.4 Project Goals 4
1.5 Required Permits/Consultations 4
1.6 Environmental Review 4
1.6.1 Endangered Species Act: Section 7 Consultation 5
1.6.2 National Historic Preservation Act: Section 106 Consultation 5
2. SITE CHARACTERIZATION 6
2.1 Regional Geology, Hydrogeology, and Local Structural Geology [40 CFR 146.82(a)(3)(vi)] 6
2.1.1 Hydrologic Setting 7
2.1.2 Site-Specific Overview 8
2.1.3 Injection Zone 10
2.1.4 Confining Zone 10
2.2 Maps and Cross-Sections of the AoR [40 CFR 146.82(a)(2), 146.82(a)(3)(i)] 11
2.2.1 Geophysical Characterization 13
2.2.1.1 Seismic Data Availability 13
2.2.2 Geologic Model (Petrel™) 14
2.3 Faults and Fractures [40 CFR 146.82(a)(3)(ii)] 15
2.3.1 Fractures 15
2.3.2 Faults 16
2.3.2.1 East Bounding Thrust Fault 16
2.3.2.2 West Bounding Thrust Fault 16

2.3.2.3 MB13 Fault 17
2.3.2.4 Southern Crestal Fault 17
2.3.2.5 West Limb Thrust Fault 17
2.3.2.6 Northern Crestal Fault (1) 17
2.3.2.7 Northern Crestal Fault (2) 18
2.3.2.8 MB12 Fault 18
2.3.2.9 Central Crestal Fault (1) 18
2.3.2.10 Central Crestal Fault (2) 18
2.3.2.11 Downdip West Flank Cross Fault 19
2.3.2.12 Northern Crestal Fault (3) 19
2.3.3 Fault Stability and Sealing Capacity 19
2.3.3.1 Pressure Compartmentalization - Seals 19
2.3.3.2 Fault Stability Analysis 21
2.3.4 Data Gaps 23
2.4 Injection and Confining Zone Details [40 CFR 146.82(a)(3)(iii)] 23
2.4.1 Depth, Areal Extent, and Thickness 23
2.4.1.1 Data Sources/ Methods 24
2.4.1.2 Injection Zone 24
2.4.1.3 Confining Zone 25
2.4.1.4 Uncertainty 26
2.4.2 Mineralogy and Petrology 27
2.4.2.1 Injection Zone 27
2.4.2.2 Confining Zones 31
2.4.3 Porosity (φ), Permeability (k), and Capillary Pressure (PC) 34
2.4.3.1 Porosity (φ) 36
2.4.3.2 Permeability (k) 39
2.4.3.3 Capillary Pressure (PC) 42
2.4.4 Injectivity, Storage Capacity, and Integrity 44
2.4.4.1 Injectivity 44
2.4.4.2 Storage Capacity 44
2.4.4.3 Integrity 45
2.5 Geomechanical Characterization [40 CFR 146.82(a)(3)(iv)] 45

2.6 Seismic History [40 CFR 146.82(a)(3)(v)] 47
2.6.1 Regional Fault Activity 49
2.6.2 Historical Earthquake Epicenters 50
2.7 Hydrologic and Hydrogeologic Information [40 CFR 146.82(a)(3)(vi), 146.82(a)(5)]. 52
2.7.1 Groundwater Occurrence within Alluvium 53
2.7.2 Groundwater Occurrence within Tulare Fm 55
2.7.3 Potential USDWs 56
2.7.4 Groundwater Occurrence within Deeper Formations 56
2.7.5 Water Supply Wells within the AoI 57
2.7.6 Potential Impact of CO_2 Injection on Potential USDWs 58
2.8 Geochemistry [40 CFR 146.82(a)(6)] 59
2.8.1 Geochemical Characterization Summary 59
2.8.2 Baseline Geochemical Characterization 60
2.8.2.1 Petrology/Mineralogy of the Injection Zone and Confining Unit 60
2.8.2.2 Characteristics of the Injection Zone Formation Water 62
2.8.2.3 Injectate Composition 64
2.8.3 Geochemical Modeling Setup 64
2.8.3.1 Model Input 65
2.8.3.2 Equilibrium Modeling 67
2.8.3.3 Reaction Pathway Modeling 68
2.8.4 Geochemical Modeling Results and Discussion 69
2.8.4.1 Equilibrium Modeling 69
2.8.4.2 Reaction Pathway Modeling 70
2.8.4.3 General Discussion of Modeling Results 71
2.9 Other Information (Including Surface Air and/or Soil Gas Data, if Applicable) 74
2.10 Site Suitability [40 CFR 146.83] 75
2.10.1 Injectivity 75
2.10.2 Confinement [40 CFR 146.83(a)(2)] 76
2.10.3 Storage Capacity [40 CFR 146.83(a)(1)] 77
3. AOR AND CORRECTIVE ACTION 79
4. FINANCIAL RESPONSIBILITY 80
5. INJECTION WELL CONSTRUCTION 81

5.1 Proposed Stimulation Program [40 CFR 146.82(a)(9)] 81
5.2 Construction Procedures [40 CFR 146.82(a)(12)] 81
5.2.1 New Drill Wells for CO2 Injection 81
5.2.2 Repurposed Wells for CO2 Injection 82
5.2.3 Repurposed Monitoring Wells 83
5.2.4 Mechanical Integrity Assurance during Well Repurposing and Drilling 83
5.2.5 Cement Bond, Temperature, and Inspection Logs 83
5.2.6 Downhole Monitoring Equipment 83

1. PROJECT BACKGROUND AND CONTACT INFORMATION

GSDT Submission - Project Background and Contact Information
GSDT Module: Project Information Tracking **Tab(s):** General Information tab; Facility Information and Owner/Operator Information tab Please use the checkbox(es) to verify the following information was submitted to the GSDT: ☒Required project and facility details **[40 CFR 146.82(a)(1)]**

1.1 Project Summary/Background

Aera Energy LLC (Aera) is submitting the following preconstruction phase application for its CarbonFrontier Carbon Capture and Sequestration (CCS) Project (Project). Aera proposes to construct and operate geologic sequestration wells located in Kern County, California. This narrative document summarizes the detailed information found in the following attachments, which are based on templates provided by the U.S. Environmental Protection Agency (EPA):

- Attachment A: CarbonFrontier Summary of Requirements
- Attachment B: CarbonFrontier Area of Review and Corrective Action Plan
- Attachment C: CarbonFrontier Financial Responsibility Demonstration

- Attachment D: CarbonFrontier Pre-Operational Well Testing Plan
- Attachment E: CarbonFrontier Testing and Monitoring Plan
    - Quality Assurance and Surveillance Plan
- Attachment F: CarbonFrontier Injection Well Plugging Plan
- Attachment G: CarbonFrontier Post-Injection Site Care (PISC) and Site Closure Plan
- Attachment H: CarbonFrontier Alternative PISC Timeframe
- Attachment I: CarbonFrontier Emergency and Remedial Response Plan
- Attachment J: CarbonFrontier Stimulation Plan
- Attachment K: CarbonFrontier Construction Details

The proposed Project is located in the Central Valley portion of unincorporated Kern County (**Figure 1.1-1**) and is primarily contained within the South and North Belridge oil fields located approximately seven miles southwest of the community of Lost Hills and west of Highway 33. Together, the two Belridge oil fields cover an area of approximately 13 miles long and three miles wide. Aera is the primary operator within both oil fields and will develop and operate the CarbonFrontier Project. **Figure 1.1-2** displays a map of pertinent features within the Area of Review (AoR) to fulfill the requirements of 40 Code of Federal Regulations (CFR) 146.82(a)(2).

The proposed Project would capture carbon dioxide (CO_2) from existing produced gas streams (pre-combustion) and emissions from existing stationary sources (post-combustion) within the South Belridge oil field and transport the CO_2 through a new, approximately 10-mile long, pipeline to the North Belridge oil field. There, the CO_2 would be injected into nine dedicated Underground Injection Control (UIC) Class VI injection wells and permanently sequestered in a depleted oil and gas reservoir, roughly 8,500 feet (ft) below the ground surface. CO_2 pipelines and associated infrastructure will be sized to also accept CO_2 from yet to-be-determined third-party sources, received by truck and pipeline. **Figure 1.1-1** displays the main Project components within the North Belridge oil field. Refer to **Table 1-1** below for a list of the proposed injection and monitoring wells. The proposed underground CO_2 sequestration field would be located within the North Belridge oil field with surface and mineral rights held by Aera and other private owners. Oil and gas production activities within the proposed underground CO_2 sequestration field would cease as a result of the implementation of the proposed Project.

As indicated above, the Project will also have the potential to receive third-party sources of CO_2, though none have been secured at this time. The Project, as proposed, will have the capacity to inject up to approximately 3.3 million metric tons per year (MM mt/yr) CO_2 starting in 2026 (pending regulatory approvals) and will operate for approximately 9.5 years, permanently sequestering a total of roughly 31.7 MM mt CO_2. Monitoring activities will occur throughout the operational life of the Project and will continue for 15 years after cessation of injection after which, the site will be closed.

CO_2 injection for the proposed Project will occur in a depleted oil and gas reservoir with saline formation water, more than a mile below any potential underground sources of drinking water (USDWs); therefore, neither an injection depth waiver nor an aquifer exemption expansion are requested.

1.2 Carbon Dioxide Capture Method

1.2.1 Pre-Combustion Capture: Process Description Summary

Aera is proposing to use an ammonia- or amine-based reactive solvent as the CO_2 capture technology on associated produced gas streams. In this process, produced natural gas from Aera's existing operations will be directed to a dedicated CO_2 capture facility in Section 32, Township 28 South, Range 21 East, Mound Diablo Base and Meridian. In that CO_2 capture facility, the produced gas stream will be passed through an absorber column where the absorbent will chemically react with and bind over 90% of the incoming CO_2. The rich absorbent carrying CO_2 will be piped to a regenerator column, where, through the combination of reduced pressure and applied heat, the CO_2 will be released and captured in nearly pure concentration. Following CO_2 release, the reconstituted absorbent will be recycled back to the absorber column. The captured CO_2 will be compressed, dehydrated, and directed to the sequestration storage site. The proposed CO_2 capture facility is expected to yield a total volume of approximately 0.2 MM mt/yr CO_2. The fully processed produced gas stream will have a carbon intensity of about 56 grams of CO_2 equivalent per megajoule ($gmCO_2e/MJ$), reduced from the preprocessing value of about 80 $gmCO_2e/MJ$.

1.2.2 Post-Combustion Capture: Process Description Summary

Aera is proposing to use an amine-based reactive solvent as the post-combustion capture technology. In this process, flue gas from several existing stationary sources (e.g., steam generators and cogeneration facility) will be ducted to a dedicated CO_2 capture facility. In the CO_2 capture facility, the flue gas will be cooled before passing through an absorber column where an absorbent will chemically react with and bind about 90 percent of the CO_2. The remaining flue gas (primarily oxygen, nitrogen, and the remaining uncaptured CO_2), will be vented to the atmosphere. The rich absorbent carrying CO_2 will be piped to a regenerator column, where, through the application of heat, the CO_2 will be released and captured in relatively pure concentration. Following CO_2 release, the lean absorbent will be recycled back to the absorber column. The CO_2 will then be compressed, dehydrated, removed of oxygen, and piped to the sequestration storage site. The proposed post-combustion CO_2 capture facilities are expected to yield a total volume of approximately 1.3 MM mt/yr CO_2.

1.2.3 Imported CO_2: Process Description Summary

California's commitment to carbon neutrality by 2045 (Executive Order B-55-18) and goal to decrease the carbon intensity of existing industries is expected to stimulate development of carbon capture projects in the state. While most projects remain speculative, Aera anticipates a need for CO_2 storage services in the future and will design the project to receive outside sources of CO_2 by truck and pipeline to supplement the pre- and post-combustion streams, up to the project's injection capacity. While these sources are not yet defined, imported CO_2 is likely to come from carbon-intensive sectors and where carbon capture incentives are in place (e.g., direct air capture, blue

hydrogen, power plants, other oil and gas operators). Imported CO_2 will be restricted to a composition specification, closely aligned with Aera's proposed pre- and post-combustion CO_2 streams.

1.3 Contact Information

Aera Energy LLC
Faisal Latif, Storage Development Manager
(661) 763-6274, Faisal.latif@crc.com

1.4 Project Goals

- Construct and operate facilities and infrastructure to capture, transport, inject, and permanently sequester up to 42.6 MM Mt of CO_2 in a safe, secure, and economically feasible manner for storage, not enhanced recovery.
- Minimize new disturbance by siting and designing project facilities and infrastructure within the existing developed oil field footprint.
- Reduce the carbon intensity of Aera's produced oil and gas by capturing CO_2 from produced gas and stationary sources.
- Generate environmental, social, and economic benefits for Kern County and the State of California by implementing low carbon technologies, developing CCS infrastructure, and providing living-wage jobs in the region.
- Contribute to California's goal to achieve carbon neutrality by 2045 (Executive Order B-55-18) by integrating carbon capture in existing operations as well as ending oil and gas production from select reservoirs and repurposing them for the permanent storage of CO_2.

1.5 Required Permits/Consultations

Table 1-2 identifies local, state, and federal agencies that have or may have jurisdiction over the proposed Project. The status of each consultation is noted for each of the permits that are in progress. Note: for some permits, the Project is in the process of evaluating if a permit/approval would be needed; hence, this list will be updated to reflect changes regarding agencies that may have jurisdiction over the proposed Project.

1.6 Environmental Review

A Conditional Use Permit/Zone Change (CUP/ZC) application was submitted to Kern County Planning and Natural Resources Department on July 7, 2022, and the application was deemed complete on September 26, 2022. Issuance of a CUP is a discretionary action that requires compliance with the California Environmental Quality Act, and Kern County has determined that the proposed Project will require the preparation of an Environmental Impact Report (EIR). The EIR will analyze the environmental effects of the proposed Project and will identify measures to avoid, minimize, and mitigate environmental impacts. During the public review period of the EIR, stakeholders are consulted, including tribes, community members, and other federal, state, and local agencies. For a list of state, tribe, and territory contacts please refer to **Table 1-3**.

1.6.1 Endangered Species Act: Section 7 Consultation

Section 7(a)(2) of the Endangered Species Act requires that, for actions authorized, funded, or carried out by a federal agency, the agency shall consult with the United States Fish and Wildlife Service and/or the National Marine Fisheries Service to promote actions that will not jeopardize the continued existence of listed species or adversely modify designated critical habitat. To facilitate this consultation, the applicant prepared a biological assessment that was submitted to the EPA in December 2023.

1.6.2 National Historic Preservation Act: Section 106 Consultation

Section 106 of the National Historic Preservation Act requires a federal agency to identify and assess the effects its proposed action may have on historic properties and to afford the Advisory Council on Historic Preservation a reasonable opportunity to comment on the proposed action. Therefore, prior to issuance of a UIC Class VI Permit, the EPA must consider the effect issuance of the permit may have on historic properties. Historic properties may include prehistoric or historic districts, sites, buildings, structures, objects, sacred sites, and traditional cultural places, that are included in, or eligible for inclusion in, the National Register of Historic Places. The consultation process provides for participation by several stakeholders including, but not limited to, the State Historic Preservation

Officer, the Tribal Historic Preservation Officer, tribal, state, and local governments, Indian tribes and Native Hawaiian organizations, interested organizations, private citizens, and the public. To help facilitate this consultation, the applicant has prepared a cultural resources inventory that was submitted to the EPA in July 2023.

2. SITE CHARACTERIZATION

2.1 Regional Geology, Hydrogeology, and Local Structural Geology [40 CFR 146.82(a)(3)(vi)]

The Area of Interest (AoI) includes the North Belridge oil field and adjacent area and is described further in **Sections 2.2** and **3.0**. The AoI is located along the western side of the southern San Joaquin Basin, within the southern portion of California's Central Valley. The San Joaquin Basin is part of the Great Valley geomorphic province, which forms an asymmetrical structural trough approximately 400 miles long and approximately 50 miles wide in Central California (**Figure 2.1-1**; Bailey 1966).

The Great Valley formed in the Mesozoic Era as a forearc basin between the subducting Farallon plate and associated Franciscan subduction complex to the west and the Sierra Nevada magmatic arc to the east (Ingersoll 1979, 1982; Dickinson 1995). The Jurassic to Cretaceous history of the basin is recorded by the basement rocks, the Coast Range Ophiolite and Franciscan Complex to the west, and the Sierra Nevada Batholith to the east (**Figure 2.1-2**; Bailey and Blake 1974; Wentworth et al. 1984; Hosford Scheirer and Magoon 2007). Over 30,000 ft of sedimentary rocks infill the basin, recording approximately 100 million years (m.y.) of sedimentation (**Figure 2.1-3**; Peters et al. 2007; Hosford Scheirer and Magoon 2007), which includes the shift from basin-wide depositional sequences to more localized depositional sequences (Bartow 1991). While late Cretaceous to Paleocene marine sedimentary rocks are observed in the central and northern San Joaquin Basin, they have not been identified within the lateral and vertical extents of the AoI near the southern end of the San Joaquin Basin (**Figures 2.1-4** and **2.1-5**; Bartow 1991; Hosford Scheirer and Magoon 2007). Late Cretaceous sedimentary rocks do occur west of the AoI within the Temblor Range (Dibblee 2006) and, therefore, are likely present within the AoI below the extent of historical petroleum exploration.

A marine depositional environment persisted in the southern San Joaquin Basin from the Paleocene through the Oligocene as the basin amassed a thick succession of mudstones and sands in bathyal to subtidal depths (Bartow 1991; Hosford Scheirer and Magoon 2007). These strata represent some of the oldest sedimentary units in the southern end of the basin (i.e., the Eocene Kreyenhagen Formation [Fm]) (Hosford Scheirer and Magoon 2007).

In the Oligocene, approximately 30 m.y. before present (Ma), subduction of the East Pacific Rise caused a dramatic shift from a convergent to transform continental margin, establishing the San Andreas Fault (SAF) (Atwater 1970; Atwater and Molnar 1973; Page and Engebretson 1984; Bent 1985) and marking the end of basin-wide depositional sequences (**Figure 2.1-6**; Blake et al. 1978; Bartow 1991). The deposition of the Temblor Fm along the western margin of the southern San Joaquin Basin coincided with this change in tectonic regime and this formation contains the injection zone "64 Zone" turbidite sands facies (regionally recognized as the Wygal Member consisting of the "Bloemer" or "First Phacoides" Sandstone, and "Main Phacoides" or "Wygal" Sandstone) and the primary confining zone facies of the Lower Santos Shale (Bent 1985; Carter 1985; Taylor and Soule 1993; Hosford Scheirer and Magoon 2007).

The Temblor Fm is stratigraphically complex and comprises up to three unconformities and four depositional sequences in the southwestern San Joaquin Basin and within the AoI (Bent 1985; Johnson and Graham 2007). In the central San Joaquin Basin, west of present-day Fresno, the Temblor Fm consists of a single marine sandstone facies (Cooley 1985; Hosford Scheirer and Magoon 2007). In contrast, on the western side of the central San Joaquin Basin, near Coalinga, the Temblor Fm consists of complexly bedded basal conglomerates, sandstones, siltstones, and claystones of variable thickness (Bridges and Castle 2002). In the southwestern San Joaquin Basin, the Temblor Fm comprises interbedded deposits of shales and sandstones (Bent 1985; Carter 1985; Callaway 1990; Johnson and Graham 2007). Many of the distinctive beds of the Temblor Fm observed on the southwestern side of the basin have equivalent/similar deposits on the southeastern side (Callaway 1990; Hosford Scheirer and Magoon 2007), although some shale deposits appear to be continuous across the axis of the San Joaquin Basin, that is, approximately 10 miles to the east of the North Belridge oil field (Bartow 1990; Callaway 1990; Hosford Scheirer and Magoon 2007). Transpression along the SAF resulted in localized uplift (i.e., the Diablo Range) and partially isolated the San Joaquin Basin from the Pacific Ocean to the west (Nilsen 1984; Bent 1985; Graham and Williams 1985; Bartow 1991). Over time, this restriction deprived the basin of oxygen, creating conditions for abundant diatom blooms and the deposition of thousands of feet of bio-siliceous mudrocks of the Miocene Monterey Fm, which overlies the Temblor Fm (Graham and Williams 1985; Johnson and Graham 2007).

Continued transpression along the SAF during the Mio-Pliocene led to the continued folding and uplift in the Temblor and Diablo Ranges, as well as the formation of many of the NW-SE trending fold-belts on the west side of the San Joaquin Basin (Harding 1976; Blake et al. 1978; Bartow 1991). The resulting anticlines, synclines, and faulted structures have contributed to the localization of hydrocarbon resources in the region, serving as structural traps and delineating most of the existing oil fields in the area (**Figure 2.1-7**; Harding 1976).

Progressive right-lateral slip along the SAF continued through the Pliocene, gradually closing off the basin from any marine influence. The resulting sedimentary deposits record the gradual transition from a shallow marine (Pliocene Etchegoin Fm), marginal marine (Plio-Pleistocene San Joaquin Fm), to freshwater lacustrine and fluvial (Pleistocene Tulare Fm) depositional environments and document the final stages of the San Joaquin Basin fill (Bartow 1991; Hosford Scheirer 2007).

2.1.1 Hydrologic Setting

The San Joaquin Valley Groundwater Basin is located within the San Joaquin River and Tulare Lake hydrologic regions . The southern and largest portion of the San Joaquin Valley Groundwater Basin lies within the Tulare Lake hydrologic region. The San Joaquin Valley Groundwater Basin consists of nine groundwater subbasins: Kings, Westside, Kaweah, Tulare Lake, Pleasant Valley, Kettleman Plain, Tule, Kern County, and White Wolf (Central Valley Regional Water Quality Control Board [RWQCB] 2008). The Kern County Groundwater Subbasin has an area of 3,040 square miles and is the southernmost division of the San Joaquin Valley Groundwater Basin (California Department of Water Resources [DWR] 2003). The AoI is located within the southwestern portion of the Kern County Groundwater Subbasin (**Figure 2.1-8**).

Groundwater occurs in disconnected, isolated locations scattered between oil-bearing zones throughout the southwestern San Joaquin Valley, with several large groundwater basins underlying the valley floor. In the western portion of the Kern County Groundwater Subbasin, the continental Pleistocene-aged Tulare Fm consists of poorly consolidated, interbedded, oxidized to reduced sands, gypsiferous clays, and gravels derived from the Temblor Range (DWR 2003). Additionally, within the Tulare Fm are interbedded clay layers of lacustrine origin (i.e., the regional Corcoran Clay) (Croft 1972; Gillespie et al. 2019). The Tulare Fm is locally overlain by the Pleistocene age Older Alluvium, which consists of poorly consolidated to cemented lenticular deposits of clay, silt, sand, and gravel (Bean and Logan 1983; DWR 2003). These deposits are often indistinguishable from the underlying Tulare Fm and are primarily exposed along the basin margins. The Older Alluvium is not present within the AoI. The uppermost deposit in the western portion of the Kern County Groundwater Subbasin and North Belridge oil field is the Holocene age continental Alluvium, composed of unconsolidated deposits of interstratified beds, stringers, and lenses of sand, silt, clay, and gravel also sourced from the Temblor Range (Bean and Logan 1983; DWR 2003). A basal alluvial clay layer may be locally present and marks the contact between the Alluvium and underlying Tulare Fm (Gillespie et al. 2019). However, differentiation of the Alluvium and Tulare Fm from geophysical logs or boring logs is difficult due to their similar composition, provenance, and depositional processes. The Tulare Fm is typically structurally deformed from folding and faulting and overlies various marine formations. In the southwest San Joaquin Basin, the Tulare Fm has been interpreted to represent a fluviodeltaic system with fluvial, alluvial, and lacustrine deposits. The thickening of the Tulare Fm towards the basin to the east suggests concurrent deposition and structural growth of the fold-fault system (Aera and Greka Oil & Gas Inc. [Greka] 2018).

2.1.2 Site-Specific Overview

The North Belridge oil field is a northwest trending, doubly plunging anticline with dips on the west flank of approximately 45 degrees (°) and on the east flank of approximately 35° (Kaczorowski et al. 1986). The macro-structure is that of an open fold with an axial trend of 150° and axial plane dipping approximately 85° to the northeast. The field contains NW-SE striking bounding faults on either side of the anticline, a roughly N-S striking bounding fault in the southern portion of the North Belridge oil field, and a SW-NE striking fault that crosscuts the structure near its northern nose. A more detailed discussion of the faults and fractures within the AoI is presented in **Section 2.3** and a detailed description of the seismic history for the AoI is presented in **Section 2.6.**

The major stratigraphic units observed at the North Belridge oil field are shown in **Figures 2.1-9** and **2.1-10**. The proposed CO_2 storage complex for this Project lies within the Oligo-Miocene Temblor Fm. The stratigraphic units present within the AoI/North Belridge oil field include the following:

- Tulare Fm: 0.6 to 2.5 Ma
- San Joaquin Fm: 2.5 to 4.5 Ma
- Etchegoin Fm: 4.5 to 5.5 Ma

- Monterey Fm: 5.5 – 16 Ma
- Temblor Fm: 16 to 33 Ma
- Tumey Fm: 33 to 37 Ma
- Kreyenhagen Fm: 37 to 48.5 Ma
- Basement: 66 to 160 Ma

The proposed injection zone within the AoI is the "64 Zone" Sandstones of the Lower Temblor Fm. As illustrated in **Figure 2.1-9**, within the AoI, the Temblor Fm is divided into five stratigraphic Members. From stratigraphic base to the top of the Temblor Fm, these Members include: the Salt Creek/Cymric Shale Member; the 64 Zone/Wygal Sandstone Member; the Santos Shale Member; the Carneros Member; and the Media Shale Member. Where distinctive patterns of interbedded sandstone and shale are observed, individual beds may have unique names, such as the Gibson Sandstone bed within the Salt Creek Shale Member and the Agua Sandstone bed(s) within the Santos Shale Member. In some cases, a variety of names have historically been used to identify the same units at different times or places in the region, as well as in various oil field operations. The nomenclature presented in this application attempts to unify the most common naming conventions presented in literature with the operational names in common use in the North Belridge oil field. To that end, throughout this application, the Wygal Sandstone Member is referred to as the 64 Zone.

The 64 Zone Sandstones are interbedded within deep water shale deposits (the underlying Cymric/Salt Creek Shale and the overlying Lower Santos Shale) (Carter 1985; Bartow 1991; Taylor and Soule 1993). The overlying strata consist of interbedded sandstones and shales, which provide numerous thick confining layers (Lower and Upper Santos Shale, as well as the Media Shale), and monitoring zones (Agua Sandstone).

The Santos Shale is generally described as medium dark gray to dark-brownish gray clayey to silty shale that becomes siltier, sandier, and more siliceous up-section (Carter 1985; Adkinson 1973). The Santos Shale can be divided into the "Upper Santos" and "Lower Santos," separated by the Agua Sandstone (Adkinson 1973 and references therein). The primary confining zone is the Lower Santos Shale and the secondary confining zone is the Upper Santos Shale (see **Section 2.4** for further discussion). Maps, cross sections, and additional discussion on the site-specific geologic features and structures are presented in **Section 2.2**.

The Temblor Fm within the AoI is underlain by the Tumey Fm and the Kreyenhagen Fm (**Figures 2.1-9** and **2.1-10**). The Tumey Fm consists of the Oceanic Sandstone bed overlain by the Tumey Shale. The depth to the top of the Tumey Fm on the anticline is on average approximately 8,000 ft true vertical depth (TVD) below mean sea level (ft TVDss). The Tumey Fm has an average stratigraphic thickness of approximately 300 to 400 ft throughout the AoI. The lowest formation identified in well logs from the North Belridge oil field is the Kreyenhagen Fm, which consists of the Point of Rocks Sandstone Member and overlying Kreyenhagen Shale. The base of the Kreyenhagen Fm has not been penetrated by historical petroleum exploration; therefore, the stratigraphic thickness of the Kreyenhagen Fm within the AoI is unknown.

First-encountered hydrocarbon-saturated sands within the North Belridge oil field are found in the Tulare Fm near the crest and along the flanks of the anticline. Groundwater is present further east as the Tulare Fm thickens along the flanks. The Alluvium is mostly dry along the crest of the anticline structure in the southern portion of the AoI (Aera 2014; California State Water Resources Control Board [SWRCB] 2014); however, manmade perched zones of produced water exist from former produced water ponds atop the basal alluvial clay in the southern and eastern portions of the North Belridge oil field and the northern portion of the South Belridge oil field (Aera 2014, 2017; SWRCB 2014; Aera and Greka 2018), and groundwater with elevated (>10,000 milligrams per liter [mg/L]) concentrations of total dissolved solids (TDS) is present in the eastern and southern portion of the AoI (SWRCB 2018). A more detailed discussion of the hydrology and hydrogeologic information within the AoI is presented in **Section 2.7**.

2.1.3 Injection Zone

The 64 Zone Sandstones consist mainly of shaly, arkosic sands, with an overall coarsening upwards trend, and have been interpreted as turbidites within submarine fans deposited at upper bathyal depths (continental shelf-slope) (Kaczorowski et al. 1986; Callaway 1990; Taylor and Soule 1993; Aera 2002). The 64 Zone Sandstones are divided into two zones: the upper U Sandstone (referred to as "Bloemer" or "First Phacoides" in other literature) and the lower W Sandstone (referred to as "Main Phacoides" or "Wygal" in other literature), separated by a shale deposit (U Shale); the U Shale has a stratigraphic thickness of approximately 65 ft, on average, within the AoI (**Figure 2.1-11**). The W Sandstone has an average approximate stratigraphic thickness between 250 and 495 ft within the anticline structure (**Figure 2.1-12**). The stratigraphic thickness of the U Sandstone is up to approximately 155 ft to the west of the anticline, thins to approximately 55 ft on the structure towards the north, and has an average stratigraphic thickness of approximately 100 ft in the AoI (**Figure 2.1-13**). Stratigraphic thicknesses were calculated from the geologic model horizons derived from seismic and well data. The geologic model is discussed in detail in **Section 2.2**. A list of wells and thicknesses calculated from the geologic model are provided in **Appendix 2A**.

The lateral continuity of the 64 Zone Sandstones of the Temblor Fm is limited to the southwestern San Joaquin Basin, extending approximately 25 miles from the North Belridge oil field to the area east of the Lost Hills and the Bowerbank oil fields (**Figure 2.1-14**; Taylor and Soule 1993; Hosford Scheirer and Magoon 2007). The 64 Zone Sandstones extend to the south to the Cymric and Belgian Anticline oil fields (Callaway 1990; Taylor and Soule 1993) and as far south as approximately 35 to 40 miles to the Buena Vista oil field and abandoned Capitola Park oil field (Hosford Scheirer and Magoon 2007). The northernmost extent of the unit within the San Joaquin Basin is just past the Devils Den oil field approximately 30 miles north of North Belridge oil field (**Figure 2.1-14**; Bartow 1990; Callaway 1990; Hosford Scheirer and Magoon 2007).

2.1.4 Confining Zone

The 64 Zone Sandstones are overlain by the Santos Shale Member. The Santos Shale Member is divided into the Upper Santos Shale, the Agua Sandstone, and the Lower Santos Shale, with the Lower Santos Shale forming the primary confining zone for the proposed CO_2 storage complex.

The Santos Shale is a dark brown to gray shale with varying amounts of silt or sand (Carter 1985) and has been interpreted as bathyal deposits formed in a marine basin along the slope and the basin plain (Adkinson 1973; Carter 1985, Johnson and Graham 2007). The Lower Santos Shale has an average stratigraphic thickness of approximately 250 ft, with a maximum stratigraphic thickness of approximately 375 ft (**Figure 2.1-15**). Regionally, the Santos Shale, as a whole, has a maximum stratigraphic thickness of 2,000 to 2,300 ft (Adkinson 1973).

In the southern portion of the AoI, the continuity of the Agua Sandstone is less well constrained. The net-to-gross (NTG) ratio in the Agua Sandstone varies across the AoI. The Agua Sandstone thins in the southern portion of the AoI, consistent with observations in published literature (Carter 1985; Johnson and Graham 2007; Mitchell 2018), where it has a low NTG ratio, indicating that it is a lower quality reservoir and that its permeability is more heterogeneous. Despite this, there is an identifiable Agua Sandstone bed (or several beds) in well logs across the AoI.

The Santos Shale Member has a similar lateral distribution as the 64 Zone Sandstones, extending approximately 25 miles to the north to Devils Den oil field and further south near the abandoned San Emedio oil field approximately 47 miles from the North Belridge oil field (**Figure 2.1-14**; Hosford Scheirer and Magoon 2007). The eastern extent of the Santos Shale is poorly constrained but has been identified in a well by Hosford Scheirer and Magoon (2007) located approximately 25 miles from the North Belridge oil field in the area east of the Bowerbank oil field.

Detailed discussion of the injection and confining zones, including the depth and thickness, as well as their porosity, permeability, mineralogy, and geochemical characteristics is presented in **Sections 2.4** and **2.8**. Geomechanical and petrophysical information for the confining zone is presented in **Section 2.5**.

2.2 Maps and Cross-Sections of the AoR [40 CFR 146.82(a)(2), 146.82(a)(3)(i)]

The proposed 64 Zone injection reservoir was discovered in 1931 and has been developed through primary production and secondary recovery with water and gas injection. Original reservoir conditions consisted of a connate water leg, oil leg, and a gas cap. Decades of production have resulted in a depleted hydrocarbon system with mixed-phase liquids throughout the structure. To date, more than 164 wells have been drilled into and through the 64 Zone Sandstones (**Figure 2.2-1; Appendix 2B**). There are shallower oil and gas reservoirs that are vertically isolated from the 64 Zone and that continue to be produced today. Exploration and operation activities provide extensive information from the field, forming a comprehensive database including two-dimensional (2D) and three-dimensional (3D) seismic surveys (discussed below), conventional core, electric logs, and substantial production data. These data were assembled to assess the feasibility of geologic sequestration. Structural maps and cross sections were generated using the Petrel™ software platform (model parameters discussed below). The geologic model utilized well logs from 151 wells which penetrate the 64 Zone (**Appendix 2B**) as the primary input, and 2D and 3D seismic data as secondary inputs.

The AoI first presented in **Section 2.1**, corresponds to the geologic model boundary (discussed below). The North Belridge oil field and the proposed storage complex is defined by a northwest trending, doubly plunging anticline. The anticline has an axial trend of 150° and the axial plane

dips approximately 85° to the northeast. The west limb of the anticline dips approximately 45° to the southwest, and the east limb dips approximately 35° to the northeast (**Figures 2.2-2**, **2.2-3,** and **2.2-4**; Kaczorowski et al. 1986). The AoR (described in detail in **Section 3** and **Attachment B**) is the maximum extent of the modeled pressure front induced by injection of CO_2.

The stratigraphic units identified in well logs and penetrated by historical drilling operations within the AoR range from the Oligocene Kreyenhagen formation to the Pleistocene Tulare formation. The internal stratigraphy of individual Members is discussed in **Section 2.1** (see **Figure 2.1-9**). The proposed underground CO_2 sequestration project is in the Temblor Formation. The 64 Zone U and W Sandstones are the proposed injection zone, and the Lower Santos Shale is the primary confining zone (see **Sections 2.1** and **2.4** for further discussion). Petrophysical well logs from key wells within the AoI illustrate the internal stratigraphy above and below the injection and confining zones (**Figure 2.2-5**).

Within the AoI, there are two potential USDWs: the nonexempted portions of the Tulare Fm and the Alluvium. Within the AoR, however, only those nonexempt portions of the Tulare Fm are considered potential USDWs, as the Alluvium is either dry or the TDS concentrations in groundwater exceed acceptable limits for a USDW (see **Section 2.7** for further discussion). Therefore, the nonexempt portions of the Tulare Fm constitute the lowermost potential USDW within the AoR.

The lowermost potential USDW, where present, is separated from the proposed injection zone by more than 7,000 vertical ft of strata, including many confining zones above the Lower Santos Shale, such as the Upper Santos Shale, the Carneros Shale, and the Media Shale of the Temblor Fm. Additional confining layers exist above the Temblor Fm which help to protect any potential USDW in the Tulare. These confining layers are the McDonald Shale, Antelope Shale, Reef Ridge Shale, and shales in the Etchegoin Fm (see **Figures 2.1-9**, **2.2-3** and **2.2-4**). The potential USDWs within the Tulare Fm are further isolated from the injection zone by the multiple confining clay layers within the Tulare Fm. The injection zone is on average 7,250 ft TVD below the Tulare Fm across the AoR. The Alluvium, where present, is separated from the injection zone by a vertical distance of approximately 8,000 ft.

Using seismic and well data, the injection and confining zones were determined to be laterally continuous throughout the AoR (**Figures 2.2-6** and **2.2-7**). Regionally, the 64 Zone Sandstones extend approximately 30 miles to the north, 35 to 40 miles to the south, 25 miles to the east, and 5-6 miles to the west (Bartow 1990; Callaway 1990; Taylor and Soule 1993; Hosford Scheirer and Magoon 2007). Similarly distributed, the Santos Shale extends beyond the AoR approximately 25 miles to the north, 47 miles to the south, up to 25 miles to the east, and 5 to 6 miles to the west (Hosford Scheirer and Magoon 2007), though the eastern extent of the Santos Shale is poorly constrained. There is no evidence of pinch-out of the 64 Zone Sandstones within the western portion of the San Joaquin Valley, though the thickness of these deposits does vary. Furthermore, there is no evidence of pinch-out for either the U or W Sandstones within the AoR based on well logs and seismic data.

2.2.1 Geophysical Characterization

2.2.1.1 Seismic Data Availability

Multiple 2D and 3D seismic datasets span the AoI. Regional 2D lines (**Table 2.2-1**) acquired in 1979 and throughout the 1980s cover the largest area, with a merged 3D seismic volume consisting of overlapping 3D datasets acquired in the late 1990s and 2000s providing dense data coverage over the North Belridge oil field (**Figure 2.2-8**).

A majority of the regional 2D seismic grid was acquired as multi-client data by Western Geophysical Company using standard acquisition parameters. Select 2D lines have benefitted from more recent reprocessing; however, the bulk of the dataset consists of the original post-stack time migrations (PoSTM), typical of 1980s vintage data processing. This dataset is primarily used for regional correlations and large-scale structural features. Acquisition parameters, vintage PoSTM processing, out-of-plane energy, and steeply dipping geometries contribute to uncertainty when using this seismic dataset.

The 3D seismic data used for the subsurface mapping and site characterization of the proposed North Belridge storage complex is comprised of portions of two separate 3D surveys; the South Belridge 3D survey acquired by Global Geophysical for Aera in 2006/2007 and the Antelope Hills 3D survey (also known as NS40/Areas A-F) acquired by SOLID State Geophysical for Prime Natural Resources in 1999–2001. These data were subsequently merged and reprocessed in 2018 by Advanced Geophysical Technology using a Kirchhoff Prestack Depth Migration. The focus of this reprocessing effort was to improve structural imaging of the Temblor Fm, including better correlation between reflector dips (and overall structural geometries) to existing well picks, correlations and, where available, dip-meter data. This 3D seismic dataset is the basis for the injection zone volume, fault geometries, 3D generated surfaces using well picks, and the structural grid for the AoR model. Although this dataset benefits from denser sampling and higher end reprocessing, potential errors in the velocity model, steeply dipping geometries, ground noise, and shallow gas accumulations may cause uncertainty in interpretations. A detailed history of processing and reprocessing for the original 3D surveys and combined 3D survey can be found in **Appendix 2B**.

It is important to note that multiple processing versions of the same 3D survey utilized for site characterization have yielded very similar results in terms of temporal and spatial resolution and detectability of existing faults within the AoR. The interpreted faults from the numerous seismic processing volumes yield very similarly positioned fault planes and fault offsets. Specifically, the major bounding faults of the AoR (see **Section 2.3** for further discussion) vary, between the seismic processing volumes, by approximately +/- 5° in strike orientation and by +/- 10° in average dip. The geometry of these bounding faults is also constrained by existing well data that help corroborate the dip and strike of these faults as observed in the 3D seismic data. The fault stability analysis (see **Section 2.3.3.2** for further discussion) was assessed using the least stable strike azimuth and a range of 60° to 90° variation in dip. Consequently, using these parameters, the analysis covers a sufficient range in uncertainty to account for the resolution of the seismic interpretation. Aera will perform shale gouge ratio analysis based on the updated model.

2.2.2 Geologic Model (Petrel™)

To assess the depth, areal extent, and thickness of the injection and confining zones, well picks and interpreted 2D and 3D seismic data were used to develop a 3D static geologic model in Petrel™, a geologic modeling software package (Schlumberger 2019). The 3D static geologic model consists of 13 modelled stratigraphic horizons within a structural fault framework. The fault framework for the AoI consists of 12 faults. Two large thrust faults run the entire length of the anticline structure. The West Bounding Thrust Fault truncates in the east against the East Bounding Thrust Fault as shown in **Figure 2.2-4**. Additionally, three southern faults and seven central and northern faults exist in the AoI (**Figure 2.2-2**). For detailed discussion of faulting in the AoI, please refer to **Section 2.3**. In the horizon modeling process, the volume-based modeling algorithm was used to create a stratigraphic function based on the framework faults and the specified stratigraphy and horizon interpretation. The stratigraphic function was defined throughout the structural model but is discontinuous across faults and unconformities. The algorithm used is designed to reduce dip and thickness variations in the stratigraphic function.

Thirteen horizons were modeled within the AoI (**Figure 2.2-6**). The modeling process uses well tops as a primary input, except for wells where the vintage log quality was too poor to reliably pick a horizon. Other structural controls, including seismic interpretation for several horizons and isochore maps, were used as secondary inputs to build the stratigraphic framework and were critical to modeling the structure away from the anticline axis where the majority of well control exists. When the volume-based modeling process runs, it uses inputs from the horizons together in a 3D space to solve for the stratigraphic function simultaneously. The solution for each horizon is then inspected and refined. During the quality control (QC) process for the structural framework, anomalous well tops were identified and reinterpreted where possible.

In general, the resulting stratigraphic framework correlates with seismic reflections except where faulting creates steep dips and seismic reflection positioning becomes unreliable. The stratigraphic function relies on semiconsistent thicknesses (based on well tops) away from well control and may not follow seismic reflections where dips are high and relative positioning of reflections is not accurate. In contrast with horizon generation, faults were primarily interpreted on 2D/3D seismic data with minimal well control. In this area, seismic data provides the most robust understanding of large-scale faulting and fault geometries. Although the majority of fault properties (extent, throw, dip, etc.) were derived from seismic data, small-scale modifications to the geometries of individual faults through the modeling process were required to maintain geologic principles with respect to the structural framework. In **Section 2.3**, fault properties are presented based on seismic geometries and may not precisely match the interpretations shown on cross-sections in this section. After many QC iterations, the horizon and fault geometries converged on a geologically sound solution for the structure.

The completed model result allows for evaluation of the structure and thickness of geologic units of interest and allows for detailed investigation of the AoI. A detailed description of the structural and property modeling framework is provided in **Appendix 2B** and **Attachment B**. Additionally, planned acquisition of new log and core data from new wells will be used to validate observations made from existing data, and if needed, refine the static model (see **Attachment D**).

2.3 Faults and Fractures [40 CFR 146.82(a)(3)(ii)]

2.3.1 Fractures

There is limited data available to inform the extent and nature (i.e., fracture conductivity) of fracturing within the injection and confining zones within the AoR. Nevertheless, the assessment of two data sets within the AoI indicates that the primary confining zone is only very slightly fractured and the injection zone is effectively unfractured. Consequently, fractures are expected to have negligible influence on the sealing capacity of the primary confining zone and the transmissivity of the injection zone. Extended range micro-imager (XRMI) logs were available for the Shideler 1-28 well, and oil-based microimager (OBMI) logs were collected for the Thebe 888N-12 well (see **Figure 2.2-2** for well locations). Both wells are outside the AoR, but within the AoI. XRMI logs were collected and interpreted by Halliburton. Compiled fracture data are provided in **Appendix 2C**.

For the Shideler 1-28 well, eight types of discontinuities were identified in the XRMI fracture frequency logs and include: conductive fractures, partial conductive fractures, resistive fractures, partial resistive fractures, induced fractures, borehole breakout, faults, and micro-faults. Drilling-induced fractures were logged for representative samples only and not every occurrence of this fracture type was logged or attempted to be logged. The Lower Santos Shale occurs from 9,006 to 9,186 ft measured depth (MD) and was logged from 9,013 to 9,156 ft MD, with the upper 7 ft and basal 20 ft not logged. Within the logged 143 ft of the Lower Santos Shale, 106 discontinuities were noted, including eight resistive fractures, two induced fractures, one conductive fracture, and one possible subvertical fault. The other 94 discontinuities were attributed to bed boundaries/bedding. With a total of nine non-induced factures over 143 logged ft, the measured average fracture density within the primary confining zone of Lower Santos Shale is approximately 0.06 fractures/linear foot. The nine measured fractures were oriented sub-parallel to the borehole, with dips ranging from 75° to 87° either to the southeast or the northeast. The U Sandstone occurs from 9,186 to 9,219 ft MD and was not logged. The W Sandstone occurs from 9,256 to 9,573 ft MD and was logged from 9,288 to 9,568 ft MD; the basal 4 ft and the upper 33 ft were not logged. Within the logged 280 ft of the W Sandstone, 115 discontinuities were noted: four induced fractures and 111 attributed to bed boundaries/bedding.

OBMI logs collected for the Thebe 888N-12 well identified six types of discontinuities, including the following: bedding, carbonate-cemented bedding, cross bedding, internal bedding, fracture, and resistive fracture. The Lower Santos Shale occurs from 8,793 to 8,988 ft MD and was logged from 8,793 to 8,805 ft MD. The U Sandstone occurs from 8,988 to 9,117 ft MD and was logged from 9,095 to 9,105 ft MD. The W Sandstone occurs from 9,166 to 9,507 ft MD and was logged from 9,193 to 9,497 ft MD. Within the 12-foot, 10-foot, and 304-foot intervals logged from the Lower Santos Shale, U Sandstone, and W Sandstone, respectively, 76 discontinuities were identified, each related to bedding.

The data available from both these wells identified only nine non-induced fractures over the 155 logged ft of the primary confining zone, and zero non-induced fractures over 584 logged ft of the injection zone. More data will be collected with a borehole formation microresistivity imaging tool

from new injection wells installed for the proposed CO_2 storage complex to assess the extent and presence of fractures within the injection and confining zones.

2.3.2 Faults

Twelve faults with measurable vertical offset have been identified within the AoI and have been incorporated into the 3D static geologic model. None of the faults identified within the AoI offset Quaternary strata or have ground surface expressions and are consequently interpreted to be inactive. Fault geometries and offsets are interpreted based on a combination of 2D and 3D seismic data correlated with well log data, where available. In addition, pressure data has been used, where available, to validate fault compartmentalization. For more detailed discussion of seismic data and processing methods, see **Section 2.2**.

Faults within the AoI, based on the seismic data, are discussed individually below. Four of the identified faults form the boundaries of the AoR, and an additional six are contained within the AoR and transect the injection zone. The characteristics of the faults within the AoI are summarized in **Table 2.3-1**, including a comparison between the vertical offset of the injection zone based on the seismic data/interpretation, and the vertical offset based on the geologic model. The fault locations relative to the top of the injection zone for the proposed CO_2 storage complex (top of the U Sandstone) are illustrated in **Figures 2.3-1** and **2.3-2**. **Figures 2.3-3** through **2.3-6** present 2D seismic cross sections, which illustrate the geometry of many of the faults identified within the AoI relative to the 13 modeled stratigraphic horizons in the 3D static geologic model (see **Section 2.2** for model details). Fault properties presented in the text below are based on seismic interpretation.

2.3.2.1 East Bounding Thrust Fault

The East Bounding Thrust Fault bounds the North Belridge anticline to the northeast and extends over 8 miles along the entire length of the North Belridge oil field. This fault defines the northeastern edge of the AoR. The fault has an average strike of 130° and an average dip of 35° to the southwest, but is interpreted to progressively flatten with depth, soling into the basement. The vertical extent of the fault is limited to the Reef Ridge Member of the Monterey Fm where it terminates at an average depth of 4,500 ft TVDss. The fault is interpreted to have accommodated primarily reverse motion. The vertical offset within the 64 Zone varies along strike with a maximum offset of over 700 ft in the southern portion of the AoI and approximately 500 ft of offset in the central portion of the AoI. Vertical offset continues to progressively decrease to the northwest and the fault terminates near the northwest edge of the AoI.

2.3.2.2 West Bounding Thrust Fault

The West Bounding Thrust Fault bounds the North Belridge anticline and the AoR to the southwest and extends over seven miles along the entire length of the North Belridge oil field. The fault has an average strike of 330° and an average dip of 40 to 45° to the northeast. This fault is interpreted as antithetic to the East Bounding Thrust Fault within the Tumey Fm. The vertical extent of the fault is limited to the Upper Reef Ridge Member of the Monterey Fm where it terminates at an average depth of 2,500 ft TVDss. The fault is interpreted to have accommodated primarily reverse motion.

The vertical offset of the 64 Zone ranges from greater than 300 ft in the southern portion of the AoI to approximately 200 ft in the central portion of the AoI. Vertical offset progressively decreases to the northwest where the fault terminates towards the northern-most extent of the AoI.

2.3.2.3 MB13 Fault

The MB13 fault transects the North Belridge anticline to the southeast and extends across the entire width of the structure for approximately 3 miles. This fault defines the southern boundary of the AoR. The fault has an average strike of 180° and an average dip of 75° to the west. MB13 is a scissor fault as its apparent sense of slip changes from reverse in the northern portion of the fault to normal in the southern portion of the fault, which may be the result of differential uplift and rotation of the northern and southern structural segments of the North Belridge anticline. Given the tectonic history and development of the San Joaquin Fold Belt (Harding 1976), the right-stepping nature from the South Belridge anticline to the North Belridge anticline would be consistent with the interpretation of the MB13 fault motion. The vertical extent of the fault extends into the Etchegoin Fm where it terminates at an average depth of 2,000 ft TVDss. The vertical offset of the 64 Zone ranges from 200 to 300 ft in the southern and central portions of the fault, decreasing to 100 to 150 ft in the northern portion of the fault.

2.3.2.4 Southern Crestal Fault

The Southern Crestal Fault is truncated by MB13 at its southern limit and extends approximately 1 to 1.5 miles to the northwest within the anticline structure. The fault has an average strike of 145° and an average dip of 80° to the southwest. This apparent reverse-offset fault has a vertical extent limited to the Media Shale Member of the Temblor Fm where it terminates at an average depth of approximately 5,500 ft TVDss. The vertical offset of the 64 Zone ranges from 150 to 200 ft in the southern and central portions of the fault to 50 to 100 ft near the northwest termination point.

2.3.2.5 West Limb Thrust Fault

The West Limb Thrust Fault is oriented subparallel to the West Bounding Thrust Fault and extends from its apparent northern termination at the Northern Crestal Fault (2) for approximately 2 miles to the southeast. The fault is interpreted to splay off the East Bounding Thrust at depth. The fault has an average strike of 315° and an average dip of 35° to the northeast. The vertical extent of the fault is limited to the Santos Shale Member where it terminates at an average depth of approximately 6,800 ft TVDss. The fault is interpreted to have accommodated primarily reverse motion. The vertical offset of the 64 Zone varies along strike from approximately 200 ft in the southeastern portion of the fault to approximately 50 to 100 ft in its northwestern limit. Offset gradually decreases to the northeast towards its termination point.

2.3.2.6 Northern Crestal Fault (1)

The Northern Crestal Fault (1) extends about 1 mile northwest within the northwestern portion of the anticline structure. This apparent reverse-offset fault is antithetical to the West Limb Thrust Fault. The fault has an average strike of 130° and an average dip of 70° to the southwest. The fault extends up into the Media Shale Member of the Temblor Fm where it terminates at an average

depth of approximately 6,000 ft TVDss. The fault is interpreted to have accommodated primarily reverse motion. The vertical offset of the 64 Zone ranges along the strike of the fault from approximately 50 to 100 ft in the northwestern segments of the fault to 100 to 150 ft in the central portion of the fault. There is little to no offset towards southeast where the fault terminates. The northern termination point is at the intersection with Northern Crestal Fault (2). Northern Crestal Fault (3), located outside the AoR, may be a continuation of Northern Crestal Fault (1), offset by Northern Crestal Fault (2).

2.3.2.7 Northern Crestal Fault (2)

The Northern Crestal Fault (2) extends in a northeast to southwest direction approximately 1 mile orthogonally across the North Belridge anticline and defines the northern boundary of the AoR. This normal offset fault extends from the southwestern limb of the anticline to the northeastern limb. The fault has an average strike of 240° and an average dip of 85° to the northwest. The vertical offset of the fault extends into the Media Shale Member of the Temblor Fm where it terminates at an average depth of approximately 6,000 ft TVDss. The 64 Zone's vertical offset ranges from about 100 ft in the fault's western and central portions to less than 50 ft towards the east.

2.3.2.8 MB12 Fault

The MB12 fault transects the North Belridge anticline with an approximate 1-mile lateral extent and is interpreted as a subsidiary fault to the larger MB13 fault. This fault has an average strike of 200° and an average dip of 75° to the northwest. The vertical extent of the fault extends into the Etchegoin Fm where it terminates at an average depth of approximately 2,000 ft TVDss. The fault is interpreted to have accommodated a right-lateral oblique (transpressional) slip. The vertical offset within the 64 Zone ranges from 50 to 150 ft in the southern and central portion of the fault to <50 ft in the northern extent of the fault. Although it is difficult to resolve this fault with the seismic data, the fault is interpreted to be truncated by the West Bounding Fault at depth.

2.3.2.9 Central Crestal Fault (1)

The Central Crestal Fault (1) extends for approximately 0.5 miles on the northeastern flank of the North Belridge anticline. This fault has an average strike of 110° and an average dip of 85° to the southwest, sub-parallel to the Northern Crestal Fault (1), and may be genetically related to that fault. The vertical extent of the fault is limited to the Media Shale Member of the Temblor Fm where it terminates at an average depth of approximately 6,000 ft TVDss. The fault is interpreted to have accommodated primarily reverse motion. The vertical offset of the 64 Zone is approximately 150 ft in the southern portion of the fault and progressively decreases to the northwest where it abruptly terminates.

2.3.2.10 Central Crestal Fault (2)

The Central Crestal Fault (2) extends for 0.5 miles across the crest of the North Belridge anticline, with an average strike of 80° and an average dip of 85° to the southeast. It is interpreted to splay off the West Limb Thrust Fault at depth and terminates at the Central Crestal Fault (1). The vertical extent of fault is limited to the Media Shale Member of the Temblor Fm or Lower Monterey Fm

and terminates at an average depth of approximately 5,000 ft TVDss. The fault is interpreted to have accommodated primarily normal motion. The vertical offset of the 64 Zone ranges from 50 to 100 ft along the length of the fault.

2.3.2.11 Downdip West Flank Cross Fault

The Downdip West Flank Cross Fault is outside of the AoR, but within the AoI, and extends for approximately 1.5 miles to the west of the North Belridge anticline and within the footwall of West Bounding Thrust Fault. The fault has an average strike of 255° and an average dip of 80° to the northwest. The vertical extent of the fault is limited to the Upper Santos Shale where it terminates at an average depth of approximately 6,000 ft TVDss. The fault is interpreted to have accommodated primarily reverse motion. The vertical offset of the 64 Zone ranges from 250 to 300 ft in the eastern to central portions of the fault to zero at its western termination point. The footwall of this fault appears to correspond with the structural low of the 64 Zone to the south (see **Figures 2.2-1** and **2.2-2**) where the depth to the top of the U Sandstone reaches up to 13,500 ft TVDss.

2.3.2.12 Northern Crestal Fault (3)

The Northern Crestal Fault (3) is outside of the AoR, but within the North Belridge anticline and the AoI, and extends for approximately 0.5 miles to the northwest from its termination point at the Northern Crestal Fault (2). The fault has an average strike of 125° and an average dip of 85° to the southwest. This nearly vertical fault is interpreted to splay off of the Western Bounding Thrust Fault and may be a continuation of Northern Crestal Fault (1). The vertical extent is limited to the Media Shale Member of the Temblor Fm where it terminates at an average depth of approximately 6,000 ft TVDss. The vertical offset of the 64 Zone ranges from 50 to 100 ft across the fault.

2.3.3 Fault Stability and Sealing Capacity

2.3.3.1 Pressure Compartmentalization - Seals

The 64 Zone is a multiphase fluid reservoir composed of a free gas cap, oil, and saline water. Pressure data were collected from oil- and gas-producing wells throughout the North Belridge oil field with pressure data from only the 64 Zone collected from wells shown in **Figure 2.3-7.** These pressure data are provided in **Appendix 2C**.

Static pressure measurements collected from the 64 Zone Sandstones were used to demonstrate compartmentalization and barriers to flow in the injection zone within the AoR. To compare pressure data from across the North Belridge oil field collected from different depths and locations within the fluid column, pressure data were normalized to a reference depth of 7,700 TVDss using an oil gradient of 0.321 pounds per square inch per foot (psi/ft) (Kaczorowski et al. 1986).

The production and reservoir history of the 64 Zone is described in detail in Kaczorowski et al. (1986). The 64 Zone pressure data (**Figure 2.3-8**) reflect the development history of the reservoir within the AoR. The rapid production of the reservoir from 1935 to 1941 was marked by a sharp decline in reservoir pressure from the initial reservoir pressure of 4,125 psi to 1,750 psi in 1941 (Kaczorowski et al. 1986). The pressure decline was arrested with the onset of gas injection and

reservoir pressure stabilized until injection activities ceased in 1947. Continued production without gas injection resulted in a rapid decline in pressure to approximately 1,150 psi. Gas injection activities resumed in 1950 and the reservoir pressure recovered. The continued production along with gas injection led to a steady decline in reservoir pressures since the 1960s.

Recent pressure data collected in 2022 from wells 25-26N and 2A-22N located within the AoR had pressure measurements from the 64 Zone of approximately 700 psi. Conversely, in 2020, when well 1-28—located on the downthrown block of the West Bounding Thrust Fault, north of the Downdip West Flank Cross Fault and outside the AoR—was perforated within the 64 Zone, it was observed that the well flowed oil and water to the surface. This production demonstrated that the 64 Zone pressures west of the West Bounding Thrust Fault are much greater than those within the North Belridge anticline structure and AoR. This pressure differential is indicative that the West Bounding Fault acts as a pressure seal to the main 64 Zone in the AoR.

The bulk of the historical production was concentrated along the flanks of the anticline within the AoR. A portion of the production came from a fault block north of the Northern Crestal Fault (2), which defines the northernmost limits of the AoR and modeled CO_2 plume. As illustrated on **Figure 2.3-9**, the reservoir pressures to the north of this fault do not follow the same trend as the main reservoir compartment. Wells to the north of the fault show a more gradual decrease in pressure and more variability in pressure measurements, before rebounding and repressurizing to a greater extent than seen in wells within the AoR (shown in blue). Historically, there has been no injection north of the Northern Crestal Fault (2); therefore, the rebound in pressure is not related to gas injection but is due to some other mechanism. The repressurization of the northern fault block suggests that, north of the Northern Crestal Fault (2), the 64 Zone could be connected to a saline aquifer that equilibrated within the produced area, contributing to the pressure rebound. Overall, the pressure data to the north of the Northern Crestal Fault (2) suggest that this area is isolated from the AoR, and the variability in pressure data suggests that this area is more compartmentalized compared to the 64 Zone to the south of this fault.

The 64 Zone pressure data from within the AoR and pressure differentials across the Northern Crestal Fault (2) suggest lateral containment within the 64 Zone reservoir in AoR.

In 2011, well 888N-12 was drilled south of the MB13 fault outside of the AoR. The formation pressure, measured with a Modular Dynamic Tester tool, was provided in a formation pressure test log in the 64 Zone and was approximately 4,000 psi, which is close to the original reservoir pressure for the main compartment of the 64 Zone reservoir. In comparison, historical pressure data from just north of MB13 and recent pressure data from within the AoR, indicated pressures of 1,150 psi and approximately 700 psi, respectively (**Figure 2.3-10**). The pressure data from the 64 Zone indicate that the MB13 fault is sealing and that well 888N-12 is in a separate compartment of the 64 Zone than the AoR.

Kaczorowski et al. (1986) reported that the sealing capacity of the East Bounding Thrust Fault was poorly constrained. The evidence available at the time suggested it to be potentially leaky, based on the apparent pressure depletion of the 64 Zone on the footwall side of the fault. However, historical reservoir pressures and current reservoir behavior, such as lack of water influx, suggest

that the 64 Zone is isolated from other permeable formations across the East Bounding Thrust Fault. Additionally, for numerical modeling of the AoR to successfully replicate the observed pressure history of the 64 Zone and maintain an underpressurized reservoir (of approximately 700 psi), the bounding faults must be sealing to prevent re-pressurization of the reservoir. For further discussion see **Section 3** and **Attachment B**.

Vertical containment is illustrated considering the pressure differentials between the 64 Zone Sandstones and the Agua Sandstones (overlying the primary confining unit). Pressure data from only the Agua Sandstone were collected from wells shown on **Figure 2.3-11** and the data are provided in **Appendix 2C**.

The pressure data from the Agua Sandstone show a different trend than those from the 64 Zone (**Figure 2.3-12**). As the 64 Zone was depleted during early production (1935–1941), the pressures in the Agua Sandstone showed no pressure change until production started from that reservoir in the early 1950s. This behavior illustrates that the Agua Sandstone is isolated from the deeper 64 Zone Sandstones. Additional pressure data from the Agua Sandstone will be gathered to illustrate the current pressure differential between the two sandstone units and further demonstrate vertical containment and isolation from the proposed injection zone.

The trends in 64 Zone pressures and the differences in reservoir pressures from outside the main fault block demonstrated sealing faults and reservoir compartmentalization, which will act to confine the CO_2 within the injection zone. Additional pressure measurements are planned to be collected from the Agua Sandstone within the AoR and from the 64 Zone north of the Northern Crestal Fault (2) and the AoR boundary.

2.3.3.2 Fault Stability Analysis

Faults can either act as seals or potential pathways for fluid migration and need to be considered in injection operations. Faults are inactive when effective normal stress is high, which is inversely proportional to pore pressure. As CO_2 is injected, pore pressure increases and effective normal stress decreases, which can cause faults to reactivate and lead to unexpected CO_2 leakage and undesirable seismicity. 2D distances from the injection wells to the faults at the U Sandstone and W Sandstone intervals within the AoI are provided in **Table 2.3-2.**

Mohr-Coulomb criterion (shear failure) was used for a fault stability analysis (FSA) based on a one-dimensional Mechanical Earth Model (1D MEM) developed for the Project and described in detail in **Section 2.5**. Inputs required for the FSA include stresses, friction angle, cohesion, and dip and azimuth angles (presented in **Tables 2.5-1**, **2.5-2**, and **2.5-3** in **Section 2.5**). Based on the wellbore centric model, the discontinuity stability analysis (DSA) plug-in within Petrel™ was used for the FSA. DSA considers the relative orientation between the in-situ stresses and identified fault planes. For this analysis, fault geometries from the 3D static geologic model were used in combination with the static 3D stress tensor defined in the 1D MEM from well 888N-12. Additionally, based on the defined 1D MEM, for the upper reservoir pressure limit scenario, the dynamic reservoir model (flow grid) is overlapped by a 3D geogrid to perform the 3D stress transformation (stress distribution) and fault stability analysis.

The DSA plug-in primarily calculates the shear and normal stress on the fault/fracture plane and accounts for the specific relative orientation of the 3D tensorial stress field and the orientation of the fault/fracture surface provided. Based on the shear and normal stress, the friction coefficient (the tangent of the friction angle), and the pore pressure, several additional result quantities are calculated, including the slip tendency (or slip tolerance). The slip tendency ranges between 0.00 and 1.00, with 0.00 indicating no tendency and 1.00 indicating the risk of slippage along the plane of weakness.

The FSA using DSA was conducted for three model scenarios to cover permutations of reservoir pressure and vertical model domain. Reservoir pressure conditions analyzed were as follows: initial/pre-development conditions (base model: 0.4 psi/ft, based on current conditions at 888N-12 well location [off-structure]), pre-injection conditions (present-day depleted reservoir: 0.024 psi/ft), and post-injection conditions (4,750 psi at the datum of 7,700 ft below mean sea level), resulting in a 0.592 psi/ft pressure gradient. No reservoir pressure compartmentalization was considered, nor was the dynamic reservoir model coupled. The friction angle analyzed was the assumed most likely value of 31° (Zoback 2010). Cohesion was assumed to be zero, which is conservative compared to the measured (**Table 2.5-1**) and average modelled cohesive strength values (greater than 2,000 psi) (**Table 2.5-3**). Vertical model domains tested were the injection zone domain (top of the U Sandstone to bottom of the W Sandstone) and the full model domain (the full vertical extent of the 3D static geologic model).

The results of the FSA from the DSA plug-in indicate that the identified faults within the AoI are stable in the three pressure scenarios for friction angle = 31° and cohesion = 0 psi. Plots of the FSA results for pre-injection and post-injection conditions are presented in terms of slip tolerance (equivalent to slip tendency) in **Figure 2.3-13**. In general, fault planes with azimuth non-oriented along the maximum horizontal stress (most of the faults in the southern part of the AoI) were found to have higher slip tolerance values but below the threshold of 1.00 (stable fault indication).

A second FSA was performed using a 3D geomechanical model (which used the rock properties from the 1D MEM combined with the 3D grid and forecasted pressures from the reservoir simulation model) and predicts that the slip tendencies experienced on the faults, indicated by maximum shear and tensile stress levels of 0.58 to 0.67, respectively, are below the levels that would indicate potential slippage (greater or equal to 1.00), as described in **Attachment B**. The results of the FSA indicate that the 12 faults are stable at planned injection volumes and pressures.

Thermal effects on fault stability were evaluated in the 3D geomechanical model by using the thermal option in CMG-GEM, with a CO_2 injection stream temperature of 180 ˚F. This sensitivity case resulted in maximum shear and tensile stress levels of 0.65 and 0.68, respectively (**Table 2.5-2**). Similarly, additional sensitivity runs for injection stream temperatures from 135˚F-216˚F were run which are well documented within **Section 1.7.1** of **Attachment B**. For the base case maximum injection pressure scenario of 4750 psi, except for the tensile shear stress level when injection temperature is 135˚F, the maximum fault stress levels for all the cases of injection temperatures from 135˚F-216˚F are estimated to be less than 0.8. Thus, a low injectate temperature causing thermal cooling effect on the stresses over the fault leading to a potential fault slippage is not foreseen until the injectate temperature differential with the reservoir temperature is as high as

40%, as described in the **Section 1.7.1** of **Attachment B**. It is to be highlighted here that this analysis considers 0.8 to be the maximum value for all stress levels which allows for a 20% safety factor from reaching either the shear or tensile failures for fault reactivation or slippage to occur.

This analysis indicates that the bounding faults remain stable for a wide range of injectate temperature variations, when considering temperature effects within the geomechanical model.

2.3.4 Data Gaps

Because none of the faults identified within the AoI have ground surface expressions, fault geometries are interpreted from 2D and 3D seismic data and correlation of well picks. Fault sealing capacity is interpreted from direct measurements of pressure differentials between fault blocks collected during the production lifespan of the 64 Zone reservoirs and are corroborated by numerical modeling based on the production/depressurization history of the 64 Zone. Additional pressure measurements will be collected from across the AoR within the 64 Zone and the Agua Sandstone. Additional fault seal analysis could be developed through direct modeling of zonal facies juxtaposition and shale gouge ratio along the bounding faults, but this analysis has not yet been completed. Additional fracture data (XRMI logs, OBMI logs, or similar) within the injection and confining zones will be collected during installation of the four new injection wells proposed for the CO_2 storage complex, which will improve the characterization of the sealing capacity of the confining zone. Fluid geochemical data are currently limited, but additional data collection through geochemical analysis of fluids from the Temblor Fm, Monterey Fm, Etchegoin Fm, and Tulare Fm could help identify oil families, evaluate the depth and extent of fluid migration, and evaluate the sealing capacity of the confining zone and faults within the AoR.

2.4 Injection and Confining Zone Details [40 CFR 146.82(a)(3)(iii)]

2.4.1 Depth, Areal Extent, and Thickness

The injection and confining zones for the proposed North Belridge CO_2 storage complex, also referred to as the AoR, are comprised of the 64 Zone Sandstones and the Santos Shale Member, respectively, of the Oligocene-Miocene Temblor Fm. At injection well sites, the stratigraphic sequence of sedimentary units consists of, from top to bottom, the following: the Tulare, Monterey, Temblor, Tumey, and Kreyenhagen Fms, underlain by locally unidentified Basement rocks at greater than 9,000 ft TVDss. The depth, thickness, and areal extent of the injection and confining zones within the AoR have been evaluated based on well logs and seismic data which, together with published research on units of interest, were used to develop a model of the proposed CO_2 storage complex in the Petrel™ software package. Details of the geometry of the injection and confining zones are presented in the following subsections of the application narrative. Within the AoR, depth and thickness of the units of interest are controlled by the Temblor Fm depositional patterns and the doubly plunging anticlinal structure of the North Belridge oil field. The anticlinal geometry will ultimately contribute to confinement and injection capacity, but the depth and thickness of the injection and confining zones vary across the AoR related to their relative position in the regional macrostructure. Discussion of injection and confining zone geometry includes the broader AoI for context of geologic conditions surrounding the AoR.

2.4.1.1 Data Sources/ Methods

To assess the depth, areal extent, and thickness of the injection and confining zones, formation tops picked from well logs and 2D and 3D seismic interpretation were used to develop a 3D static geologic model in the Petrel™ software package. A detailed description of the geologic model, including a discussion of the constituent data sources, is provided in **Section 2.2** and in **Attachment B**.

2.4.1.2 Injection Zone

CO_2 injection will target the 64 Zone Sandstones of the Temblor Fm, comprising the U Sandstone and W Sandstone and separated by the U Shale (**Figure 2.1-9**). The 64 Zone Sandstones are conformably and unconformably overlain by the Lower Santos Shale and are underlain by the Salt Creek Shale (Foss and Blaisdell 1968). Taken together, the 64 Zone Sandstones are present across the North Belridge oil field with about 600 ft of gross interval thickness (Aera 2002).

The following subsections describe in detail the areal extent, depth, and thickness of the injection zone, and **Table 2.4-1** summarizes the geometric properties of each unit that makes up the injection zone.

Areal Extent

The lateral continuity of the 64 Zone Sandstones is limited to the southwestern San Joaquin Basin and can be correlated regionally in literature. Please refer to **Section 2.1** of this application for a discussion of source literature documenting the areal extent of the 64 Zone Sandstones.

As shown in Petrel™ model outputs in **Figures 2.4-1** and **2.4-2**, the 64 Zone Sandstones extend across the entire AoI.

Depth

Figures 2.4-1 and **2.4-2** display depths of the 64 Zone U and W Sandstones in TVDss. Ground level elevation in the AoR averages 650 ft above mean sea level and can be added to reported values of TVDss to approximate depth below ground level. Within the AoR, the average depth of the top of the U Sandstone is 7,810 ft TVDss and the average depth of the top of the W Sandstone is 8,005 ft TVDss. Within the larger AoI, the depth of both units increases on the east and west limbs of the anticline.

Thickness

The U and W Sandstones of the 64 Zone each have varying thicknesses within the AoI.

Figure 2.4-3 shows the true vertical thickness (TVT) of the U Sandstone. The thickness range of the U Sandstone is 60 to 100 ft within the AoR. Within the broader AoI, the U Sandstone generally increases in thickness on the west side of the anticline and thins to the north.

Literature documentation of the U Sandstone thickness is limited; however, Kaczorowski et al. (1986) noted a varied thickness of the U Sandstone in agreement with the Petrel™ model output,

reporting unit thickness as roughly 40 ft in the northwest end of the 1973/74 oil field boundary to over 150 ft in the southeast portion of the field.

Figure 2.4-4 illustrates the TVT of the W Sandstone. Within the AoR, the interpreted thickness of the W Sandstone ranges from 260 to 600 ft TVT. Within the surrounding AoI, the W Sandstone reflects thickness patterns of the U Sandstone as it thins in the north and northeast, generally maintains an average thickness of 450 ft to the east and thickens to the west. Outside of the AoI, documentation of W Sandstone thickness is limited. Carter (1985) describes the W Sandstone as 200 ft thick, while Kaczorowski et al. (1986) reported an average W Sandstone thickness of 320 ft. Additionally, Foss and Blaisdell (1968) estimated the W Sandstone to be over 400 ft thick. The U and W Sandstones are separated by the U Shale, which has a TVT of 40 to 115 ft within the AoR.

2.4.1.3 Confining Zone

The 64 Zone Sandstones of the injection zone are conformably and unconformably overlain by the Santos Shale Member of the Temblor Fm. The Santos Shale Member is most often documented as the Upper Santos Shale (early Miocene) and the Lower Santos Shale (late Oligocene) in reference to the shale beds above and below the Agua Sandstone interbed (Foss and Blaisdell 1968; Adkinson 1973; Carter 1985). The Lower Santos Shale forms the primary confining zone, and the Upper Santos Shale forms the secondary confining zone for the proposed CO_2 storage complex.

In the southern portion of the AoI, the Agua Sandstone is characterized by a low NTG ratio, meaning that while there may be a lithologically distinctive bed present between the Upper and Lower Santos Shales, it is of poor reservoir quality/producibility relative to the Agua Sandstone in the northern portion of the AoI and is more difficult to reliably identify using traditional wireline logging tools. For example, an interval of low gamma ray values may be observed within the Santos Shale Member that is not accompanied by a significant response in spontaneous potential and resistivity indicative of a producible reservoir. Furthermore, although the lower NTG may be related to low permeability, intrinsic permeability data for the unit are not currently available in the southern portion of the AoR. However, intrinsic permeability data available from northern portion of the AoR indicate that the Agua Sandstone in the northern portion has a relatively higher permeability which aligns well with the higher NTG ratio observed in this area. The variation in thickness of the Agua Sandstone is consistent with observations in the published literature (Carter 1985; Johnson and Graham 2007; Mitchell 2018) and, although the Agua Sandstone thins to the south, there is an identifiable Agua Sandstone layer across the AoI. The boundary of the identified shift in NTG ratio is shown as the Extent of the High NTG Agua Sandstone on **Figure 2.4-5**.

The following subsections describe in detail the areal extent, depth, and thickness of the confining zone. **Table 2.4-1** summarizes the geometric properties of each unit that makes up the confining zone.

Areal Extent

The Santos Shale has a similar lateral distribution as the 64 Zone Sandstones and extends far beyond the limits or the AoR. Regional well data indicate that the Santos Shale occurs along the San Joaquin Basin's southwest margin (Hosford Scheirer and Magoon 2007). Please refer to

Section 2.1 of this application for a discussion of the available source literature documenting the areal extent of the Santos Shale.

As shown on **Figures 2.4-6** and **2.4-7** the Upper and Lower Santos Shale each extend across the entire AoI.

Depth

The depth to the top of the Upper Santos Shale, the uppermost unit of the Santos Shale Member, is on average 7,330 ft TVDss within the AoR. Within the broader AoI, the depth of the Upper Santos Shale increases on both east and west sides of the anticline and shallows to the north (**Figure 2.4-6**). The depth to the top of the Lower Santos Shale is shown on **Figure 2.4-7** and closely matches the structural form of the Upper Santos Shale. The average depth to the top of the Lower Santos Shale is 7,528 ft TVDss within the AoR.

Thickness

Figure 2.4-8 illustrates the TVT of the Upper Santos Shale. The approximate thickness of the Upper Santos Shale is 30 to 85 ft TVT within the AoR. Beyond the AoR, the unit generally maintains an average thickness of 70 ft on the east side of the anticline and shows a slightly increased thickness on the west side of the anticline.

Figure 2.4-9 illustrates the TVT of the Lower Santos Shale. Within the AoR, the Lower Santos Shale has a thickness range of 230 to 370 ft TVT. The Lower Santos Shale includes local areas of increased thickness where the Agua Sandstone thins or is characterized by a low NTG ratio. Please refer to the previously introduced **Figure 2.4-5** for modeled thickness of the Agua Sandstone. Within the AoI, the Lower Santos Shale generally maintains an average thickness of 315 ft TVT on the east side of the anticline, shows increased thickness on the west side of the anticline, and thins to the north.

Figure 2.4-10 illustrates the TVT of the total Santos Shale Member, including the Upper Santos Shale, the Agua Sandstone, and the Lower Santos Shale. Within the AoR, the thickness of the Santos Shale Member is 340 to 645 ft TVT.

Literature documentation of the Santos Shale thickness is limited. As described by both Dibblee (1973) and Adkinson (1973), an exposed reference section of the Santos Shale Member in Zemorra Creek, approximately 10 miles south of the AoI, is 275 to 295 ft thick and is divided into the Upper and Lower Santos Shale at 180 and 60 ft, respectively, by the Agua Sandstone. Foss and Blaisdell (1968) documented an Upper Santos Shale maximum thickness of 1,500 ft in the Bitterwater Creek outcrop area and documented the Lower Santos Shale as 275 ft thick at N.E. McKittrick (15 to 20 miles south-southeast of the AoI). Regionally, the Santos Shale Member has a maximum stratigraphic thickness of 2,000 to 2,300 ft (Adkinson 1973).

2.4.1.4 Uncertainty

Present understanding of the depth, thickness, and areal extent of the proposed injection and confining zones is based on the 3D static geologic model, which is inherently limited by the density, type, and quality of available data inputs. The depths of the strata of interest are understood

with high confidence at the location of wells with open-hole log data but must be interpolated and/or extrapolated where log data do not exist. In these instances, interpolation of stratigraphic horizons is guided with interpretations of 2D and 3D seismic data. In areas where wells are more sparsely distributed, or where seismic data quality is poor, the confidence of the modeled horizons is decreased. These conditions are more likely to occur along the flanks of the North Belridge anticline, where historic exploration has been limited. Additional data to characterize the geometry of the injection and confining zones, including modern petrophysical logs and cores, will be collected from each of the newly drilled injection wells proposed for the CO_2 storage complex. Details of the proposed new injection wells are provided in **Section 5**.

As outlined in the Pre-Operational Testing Plan (**Attachment D**), Aera will attempt to acquire open-hole or cased-hole logs of the newly drilled and repurposed injection wells, which will be used to confirm thicknesses and depths of the injection and confining zones. Information collected during the pre-injection period will be incorporated/compared with the geologic model. If depth/thicknesses are substantively different at well locations compared to the current geologic model, an updated model will be generated. In addition, Aera will attempt the acquisition of rotary sidewall cores during drilling of new injection wells to validate observations made from core acquired in vintage wells (described in **Sections 2.4.2** and **2.4.3** below). Rotary sidewall cores are preferred over percussion sidewall cores because of their suitability for porosity and permeability measurements. However, recovery of rotary sidewall cores can be challenging, especially considering the extent of pressure depletion in the 64 Zone Sandstones. The initial plan is to collect up to 50 plug samples per well, which would be evenly distributed through the Lower Santos Shale (primary confining zone) and the 64 Zone Sandstone (injection zone) intervals to confirm observations on vertical heterogeneity. A percussion sidewall coring tool will be available as back-up to collect up to 30 samples if rotary sidewall recovery is not satisfactory. Percussion sidewall cores are not suitable for porosity and permeability measurements, but mineralogy and lithology analyses can be performed.

2.4.2 Mineralogy and Petrology

2.4.2.1 Injection Zone

The target injection zone is comprised of the U Sandstone and underlying W Sandstone, collectively known as the 64 Zone Sandstones (**Figure 2.1-9**). The W Sandstone is the thicker, and stratigraphically deeper, of the two units. It is a well cemented, fine- to coarse-grained sandstone that is generally massive and varies from poorly sorted and subangular to very well sorted and subrounded to rounded. Visual classification of the W Sandstone is based on conventional core samples collected from wells 4-1N, 17-2N, and 43-27N within the AoR (**Appendix 2D**) and published literature (Carter 1985; Kaczorowski et al. 1986). This sandstone is typically gray in color and contains some fossiliferous and bioturbated sections (Dibblee 1973; Taylor and Soule 1993). Within the North Belridge oil field, the bottom ~50 ft of the W Sandstone is bioturbated, fine-grained, clay-rich sandstone with both horizontal and vertical burrows (Taylor and Soule 1993). The top of the basal section is scoured and overlain by ~3 ft of medium-grained, clean (minimal interstitial fines), parallel-bedded sandstone which grades into massively bedded sandstone (Taylor and Soule 1993). The remainder of the W Sandstone in the North Belridge oil

field is dominantly non-bioturbated, medium-grained, massive, clay-poor sandstone (Taylor and Soule 1993).

The upper 64 Zone Sandstone, the U Sandstone, overlies the U Shale that separates the W and U Sandstones. The U Sandstone has visual characteristics similar to the underlying W Sandstone. The U Sandstone has been similarly altered by mechanical compaction of framework grains and cementation. Cementing material comprises primarily quartz overgrowths, but also includes minor carbonate and clay mineral cements (mainly kaolinite). To the north, the reservoir quality of the U Sandstone degrades because of thinning, cementation, and possible faulting (Kaczorowski et al. 1986). To the southwest, reservoir quality degrades by cementation (Kaczorowski et al. 1986).

Quantitative characterization of the target injection zone mineralogy and petrology is based on analytical data generated for this evaluation and supplemented with information from academic studies. The dataset supporting mineralogic and petrologic characterization consists of x-ray diffraction (XRD) analyses and point-counted thin section analyses from extracted cores. A total of 44 samples from well 17-2N, seven samples from well 4-1N, and four samples from well 43-27N were collected from the W Sandstone interval of the cores and analyzed via petrographic light microscopy and point-counted using 300 points per thin section to evaluate modal mineralogy. Three additional samples from well 43-27N were collected (one from the U Sandstone and two from the W Sandstone) and analyzed via XRD to quantify mineral weight percentages. Results and depths of each sample are presented in **Table 2.8-1** in **Section 2.8**. The locations of sampled wells are shown on **Figure 2.4-11**. The injection zone dataset is inclusive of multiple wells, depths, and units and, therefore, is considered to provide a representative assessment of injection zone petrology and mineralogy.

Although data from point-count analyses and XRD analyses are not directly comparable, results of each analytical method from well 43-27N show similar abundances of quartz, feldspar, and clay minerals. Detection threshold constraints on XRD analyses do not allow minerals to be quantified at small abundances, so it is likely that minerals such as glauconite, calcite, and dolomite, which were reported as small quantities in point-count analyses, were not detected in XRD analyses despite possibly being present. Generally, available data suggest consistency between the two analytical methods. Furthermore, mineralogy analytical results presented herein are consistent with the conclusions of academic studies.

Sandstone petrology is typically classified based on the ratio of common detrital components: quartz, feldspar, and lithic (rock) fragments, referred to as a Q:F:R ratio. This ratio forms the basis of sandstone petrologic interpretation by indicating the relative proportion of common clastic components. The 64 Zone Sandstones are classified as arkosic sandstone (**Figure 2.4-12**), meaning that mineralogy of the 64 Zone Sandstones is dominated by clastic minerals quartz and feldspar. The 64 Zone Sandstones also contain various cementing minerals, including quartz overgrowth cement, clay mineral cement, and carbonate cement. Clay cements are primarily authigenically formed kaolinite, although smectite, illite, and mixed-layer illite/smectite (I/S) are present as detrital components as well. Minor amounts of carbonate cements, consisting of pore-filling dolomite and calcite, are present at an average abundance of 1.0% (based on point-count analyses

and hydrochloric acid [HCl] solubility testing). Authigenic glauconite was observed in some samples during point-count analyses (Taylor and Soule 1993).

Compositionally, the 64 Zone Sandstones' framework contains quartz, potassium feldspar (K-feldspar), plagioclase, and various lithic fragments of volcanic and metasedimentary origin (**Figure 2.4-12**; Taylor and Soule 1993; Kaczorowski et al. 1986). Abundant feldspar and higher proportions of K-feldspar relative to plagioclase indicate that these sandstones were derived from a dominantly granitic to granodioritic plutonic source terrain (Taylor and Soule 1993).

The 64 Zone Sandstones were deposited in a submarine-fan environment. Diagenetic alteration of these sandstones generally includes the following: (1) grain compaction, which reduced porosity to an average of 20%; (2) quartz overgrowth formation/cementation, which further reduced porosity by an average of 6.2%; and (3) feldspar dissolution and subsequent precipitation of authigenic kaolinite, resulting in little to no net change in porosity (Taylor and Soule 1993). Feldspars consist of K-feldspar, observed at an average abundance of 16.5%, and plagioclase, observed at an average abundance of 10.1% (**Table 2.8-1**). Formation of four separate stages of carbonate cementation was believed to have occurred throughout the paragenetic sequence. Carbonate cements include pore-filling dolomite and calcite. These cements are absent in the majority of samples for which petrographic analyses were conducted. Carbonate cements are present at an average abundance of 1.0% (sum of calcite and dolomite) based on petrographic thin section point-count analysis, although intervals have been observed containing carbonate cements at 20 to 30% of bulk volume (Kaczorowski et al. 1986). The point-count average carbonate cement abundance of 1.0% is reinforced by HCl solubility testing completed on 64 Zone Sandstone samples. Three samples collected from well 43-27N within the 64 Zone Sandstones (one sample from the U Sandstone and two samples from the W Sandstone) yielded an average HCl solubility of 1.2%, which is similar to the average carbonate abundance quantified by point-counting. The analytical report containing HCl solubility testing results is included in **Appendix 2D**.

Quartz overgrowths comprising the cementing material were observed to be small and poorly developed in samples that were primarily cemented by calcite. Dolomite was observed as both a pore-filling cement and as an authigenic replacement of existing calcite cement. Minor amounts of secondary anhydrite cement have been reported (Kaczorowski et al. 1986). Authigenic clays are present at an average abundance of 4.7%. Mean effective porosity of the 64 Zone Sandstones was found to be 9.9%, based on visual determination from point-counting (**Table 2.8-1**), and approximately 11% to 15%, based on laboratory porosity testing (**Table 2.4-4**). Quantification of total porosity based on visual determination from point-counting is subject to potential error associated with the instrument operator's assessment of empty space and of porosity in the presence of skeletal grains and secondary cementing minerals that partially occlude pore throats but do not completely fill pore space. As such, laboratory methods specifically designed to assess total porosity provide more accurate results (**Table 2.4-4**).

Specific analysis of the clay-sized fraction within the 64 Zone Sandstones has not been completed on samples collected for this evaluation but is based on the findings of Taylor and Soule (1993). Clay minerals within the 64 Zone Sandstones include kaolinite, glauconite, illite, and mixed-layer I/S (Taylor and Soule 1993). Taylor and Soule (1993) report an average clay mineralogy

distribution of 50% I/S, 36% illite, and 14% kaolinite based on scanning electron microscope (SEM) and XRD analyses of the clay-sized fraction of eight samples. The percentage of illite in mixed-layer I/S ranges from 75% to 85%, indicating prevalent illitization of smectite. Although illitization of smectite is prevalent, distinct smectite layering was confirmed in SEM micrographs from the 64 Zone Sandstone. These SEM micrographs are provided as **Appendix 2D**. The W Sandstone also includes a basal layer that contains a greater component of detrital clay minerals (up to 16.3% by point-counting) (**Table 2.8-1**). This basal layer contains lower total porosity (2.6 to 7.9%) as a function of the increased abundance of detrital clays (Taylor and Soule 1993).

The majority of the 64 Zone Sandstones are composed of quartz and feldspar, minerals that are typically chemically inert. However, at temperature and pressure conditions relevant to the injection zone, feldspar grains in sandstones may experience dissolution or precipitation of overgrowth cements, and quartz may experience some degree of overgrowth precipitation. Often, feldspar dissolution/precipitation occurs as one side of a feldspar-clay mineral geochemical reaction (Lanson et al. 2002). Precipitation of secondary clay minerals (kaolinite and illite) at the expense of feldspar grains in deep sandstone systems is well documented. The 64 Zone Sandstones contain both detrital and diagenetically formed clay minerals that could supply mass for both sides of these reversible reactions. Alteration reactions between these clay minerals and other aluminosilicate minerals are also possible, as are alteration reactions between different clay minerals (e.g., transformation of smectite to illite). The 64 Zone Sandstones also contain a small component of carbonates as pore-filling cement. Carbonate mineral stability is highly sensitive to several conditions, including pressure, temperature, and pH (Drever 1988). Dissolution or precipitation of carbonate minerals is a likely byproduct of altering geochemical conditions in the system. Generally, a decrease in pH would be expected to initiate carbonate dissolution; likewise, increases in pH, aqueous calcium, or aqueous bicarbonate may result in carbonate precipitation. Introducing CO_2-dominated injectate gas into formation groundwater will likely result in the dissolution of some CO_2 into the aqueous phase, leading to a subsequent decrease in formation water pH levels. In turn, existing carbonate minerals within the 64 Zone Sandstones may dissolve to buffer the initial pH decrease brought on by gas injection but would be expected to reprecipitate as aqueous bicarbonate concentrations increase in formation water. Carbonate minerals account for a very small percentage of the bulk rock by volume and the effect on porosity is expected to be small.

Site-specific data were used in **Section 2.8.1** as input for geochemical modeling efforts to assess mineral stability and evaluate which reactions are likely to occur from introducing CO_2-dominated injectate gas into the geochemical system. These results are discussed in greater detail in **Section 2.8.4**. Some geochemical reactions between minerals (both precipitation reactions and dissolution reactions) are expected to occur, but the injection zone is dominantly comprised of quartz and feldspar primary grains and, therefore, solid-phase mass changes are expected to be minimal. As such, the injection zone can be characterized as compatible with the proposed CO_2-dominated injection gas stream.

Further refinement of the injection zone characterization efforts is achievable through additional sampling and analysis of existing cores. Sandstone mineralogy and petrology are well defined

using a combination of petrologic thin-section point-counting and XRD analyses, so additional analytical techniques are not required. However, performing point-counting and XRD on a greater number of samples from additional wells at additional depths would provide strong assurance that average mineralogical values used as inputs in geochemical models are representative of the entire injection zone. At present, most samples comprising the injection zone dataset were collected from the W Sandstone. Additional sampling of the U Sandstone would strengthen confidence in the representativeness of modeling inputs. To improve characterization of lateral and vertical heterogeneity, mineralogic sample collection within the injection formation (U and W Sandstones) will be attempted during drilling of new wells. As stated in the Pre-Operational Testing Plan (**Attachment D**), a subset of the sidewall core samples collected from each well (five to eight samples from the 64 Zone Sandstones) will be selected to perform mineralogy and petrology analyses. The specific depths of the samples for mineralogy and petrology analyses will be selected using well logs and will be located to capture vertical heterogeneity. Aera will also acquire open-hole or cased-hole logs of the newly drilled and repurposed injection wells that will be used to confirm mineralogy and identify vertical heterogeneity.

2.4.2.2 Confining Zones

The 64 Zone Sandstones are overlain by the Santos Shale Member of the Temblor Fm in the southwestern San Joaquin Basin. The Santos Shale is further divided and locally named as the "Lower Santos Shale" and "Upper Santos Shale" in reference to the beds below and above the Agua Sandstone (**Figure 2.1-9**; Adkinson 1973). The Lower Santos and Upper Santos Shales constitute the primary and secondary confining zones for this Project, respectively. The Lower Santos Shale is a generally massively bedded medium to dark-gray and brown claystone with very little silt or sand (Carter 1985). Occasional intervals of hard, platy siliceous shale, and platy to blocky calcareous shale are also observed.

The Upper Santos Shale comprises two general facies: dark gray to brown clay shale with thin-silt and sand-interbedded laminations, and tan, platy, siliceous and calcareous clay shales (Carter 1985; Foss and Blaisdell 1968). Although the two units are broadly similar, the Upper Santos Shale contains greater silt and sand components relative to the Lower Santos Shale (Foss and Blaisdell 1968; Carter 1985). Some shale laminations observed within the Upper Santos were found to contain lenses of glauconitic sandstone. The Upper Santos Shale is decreasingly fossiliferous with increased depth (Adkinson 1973).

The intervening Agua Sandstone (between the Lower and Upper Santos Shale) is described as having a distinct facies change corresponding to the abrupt thinning of this deposit to the south along a NE-SW striking line through the middle of the North Belridge oil field (Carter 1985; Pacific Geotechnical Associates Inc. 1997; Mitchell 2018). The northern deposits of the Agua Sandstone, roughly correlating to the northern half of the North Belridge oil field, are described as a friable, fine to coarse grained, arkosic sandstone with at least two thin oyster beds, interpreted to have a shallow marine depositional environment on a sand-rich middle shelf (Carter 1985). To the south, the Agua Sandstone is described as a fine to medium grained, phosphatic and glauconitic sandstone, with pelletal phosphorite, many of the sand-sized grains of glauconite partially phosphatized, and an organic-rich argillaceous matrix with varying amounts of siliciclastic silt and

fine sand, interpreted to represent a sediment-starved outer shelf or upper slope setting (Carter 1985).

Five samples of the Upper Santos Shale have been collected from whole core recovered from well 888N-12 (location shown in **Figure 2.2-1**) and were submitted for XRD analyses for total mineralogy and clay mineralogy, petrographic light microscope analysis of thin sections, and SEM analysis of rock chip samples. These samples were collected using 10-foot spacing from a depth interval of approximately 50 ft to address the potential for localized heterogeneity.

Mineralogy results obtained from XRD are provided in **Table 2.4-2**. While expected minor variability was observed, the five samples were found to be mineralogically similar (i.e., the samples contained similar major and minor mineral abundances). As such, these results are believed to provide a representative assessment of the Upper Santos Shale mineralogy. Samples generally consist of siltstone with detrital clay matrix material which occludes intergranular pore space. XRD was completed to quantify mineral abundances for bulk samples and clay-size fractions. Samples contained an average of 48 percent weight (wt.%) clay-sized material which is comprised primarily of mixed-layer I/S (32 wt.% average) and amorphous organic clay-size material (12 wt.% average), with minor amounts of kaolinite, chlorite, and illite. Mixed-layer I/S consists of 36% illite layers on average. Plagioclase (18 wt.% average), quartz (16 wt.% average), and calcite (11 wt.% average) comprise the majority of granular material. Siderite and pyrite cements were present at low abundances. Dolomite was present at low abundances as a replacement mineral to calcite or as fine crystals of cement locally admixed with clay matrix.

Petrographic analyses of the five samples were completed using polarized light microscopy (thin sections) and SEM (rock chips). The laboratory analytical report for these analyses is provided as **Appendix 2D**. The samples were found to consist of matrix-rich siltstone with some sand-sized fossils. The silt grains primarily consist of quartz and plagioclase. Calcite fossils are present at grain sizes larger than the clastic silt material. The fossils are dominantly composed of calcite but some were found to have been partially replaced by dolomite. Matrix material consists almost entirely of detrital clay. Organic material is observed within the matrix as well, identified by the opaque black color in thin sections. Detrital clays have experienced ductile deformation and fill nearly all intergranular porosity. Some authentic cementing materials have been identified. Pyrite framboids are observed in SEM rock chip analyses. Siderite was documented in XRD results but was not explicitly identified in petrographic analyses.

Additionally, the Santos Shale Member has been sampled, and mineralogy and petrology have been evaluated as part of academic studies of the unit. Mitchell (2018) analyzed 40 samples from five wells located in the southernmost portion of the San Joaquin Basin (within 7 to 26 miles south-southeast of the South Belridge oil field [**Figure 2.4-11**]) using XRD, X-ray fluorescence (XRF), and inductively coupled plasma mass spectrometry. These samples were collected from three distinct depth intervals: shallow burial depths ranging from 1,061 to 1,944 ft below ground surface (bgs) (as reported in Mitchell [2018]), intermediate burial depths ranging from 4,063 to 6,505 ft bgs, and deep burial depths ranging from 14,910 to 14,970 ft bgs. The Santos Shale dataset from Mitchell (2018) accounts for both spatial and depth variability and, therefore, allows for a holistic assessment of petrology of the primary and secondary confining zones.

XRD analyses from academic studies indicate that the bulk composition of Santos Shale samples comprises 45% clay minerals, 29% quartz, 15% carbonate minerals, and 11% feldspar. These results are generally corroborated by analysis of samples collected for this study (**Table 2.4-2**), although the Upper Santos Shale samples were found to contain slightly less quartz and slightly more feldspar. Similar percentages of clay minerals, carbonate minerals, and quartz + feldspar were interpreted in elemental capture spectroscopy (ECS) logs (**Appendix 2G**) over the Lower Santos Shale interval in well 888N-12 (8,794 to 8,988 ft MD; 8,055 to 8,247 ft TVDss), located within the AoI[1] (**Figure 2.2-5**). Analyses of the clay-sized fraction from academic studies indicate 45.5% smectite, 43.3% illite, 8.2% kaolinite, and 3.0% chlorite (as percentage of the clay-sized fraction). Analyses from the samples collected for this study found lower abundances of kaolinite. The average composition of the overall (Upper and Lower) Santos Shale (from both academic studies and XRD results of samples collected for this study) is classified as an argillaceous/siliceous mudstone based on the classification scheme of Gamero-Diaz et al. (2012). The carbonate component of the Santos Shale is the most reactive component, but the potential impact of carbonate reactivity is mitigated by the mudstone's low permeability and the limited surface area in contact with fluids along the injection zone-confining unit interface. As such, the Santos Shale is believed to be compatible with the proposed CO_2-dominated injection gas stream. An expanded discussion of expected confining zone mineral reactivity is provided in **Section 2.8**.

Characterization of the primary confining zone may be improved by collecting and analyzing samples from new injection wells planned for the proposed CO_2 storage complex. At present, much of the information supporting the petrologic and mineralogic assessments of the primary and secondary confining zones originates from academic studies, although analysis of core from the Upper Santos Shale was completed and constitutes a primary mineralogical data source for the secondary confining zone. Pulsed neutron wireline log measurements are planned to be conducted in the injection wells. These analyses will expand the existing primary and secondary confining zone dataset and allow for a more robust understanding of the rock properties. While geochemical modeling of injectate-influenced pore fluid interactions with the primary and secondary confining zone mineralogy was not completed as part of this evaluation, increased understanding of mineralogy and geochemistry will allow for more confident conclusions regarding the nature of injectate gas interaction with the confining zones.

Uncertainty related to the current understanding of the primary confining zone is primarily associated with the small sample size of the dataset and current reliance on external sources. The academic XRD dataset comprising the mineralogical characterization of the entire Santos Shale (Upper and Lower) consists of 40 samples. This dataset was supplemented with petrographic and XRD analyses of 5 samples from the Upper Santos Shale (secondary confining unit). These samples were found to maintain general consistency with the academic dataset as evidenced by the identical petrologic classification using averages of both datasets. Increasing the number of samples analyzed, particularly within the Lower Santos Shale (primary confining unit), would result in a better understanding of heterogeneity within the Santos Shale and allow for better-

[1] ECS logs report mineral abundance values as mineral weight fractions, as opposed to XRD analyses which report mineral abundance values as mineral weight percentages.

informed opinions regarding its mineral interactions with injectate gas. Additionally, internal collection and analysis of samples from the primary confining unit will serve to demonstrate that appropriate quality assurance (QA)/QC measures are taken during analytical work.

To improve characterization of lateral and vertical heterogeneity, mineralogic sample collection within the primary confining unit (Lower Santos Shale) will be attempted during drilling of new wells. As stated in the Pre-Operational Testing Plan (**Attachment D**), a subset of the sidewall core samples collected from each well (five to eight samples from the Lower Santos Shale) will be selected to perform mineralogy and petrology analyses. The specific depths of the samples for mineralogy and petrology analyses will be selected using well logs and will be located to capture vertical heterogeneity. Aera will also acquire open-hole or cased-hole logs of the newly drilled and repurposed injection wells that will be used to confirm mineralogy and identify vertical heterogeneity.

2.4.3 Porosity (φ), Permeability (k), and Capillary Pressure (P_C)

Having a rich history of oil and gas production from multiple reservoirs, including the U Sandstone and the underlying W Sandstone, collectively known as the 64 Zone Sandstones, the North Belridge oil field has been the subject of several reservoir characterization studies. Over the years, a significant amount of subsurface data (core description and analysis, mudlogs, wireline logs, etc.) have been collected, much of which is available in analog and/or digital format to inform the petrophysical characterization of the 64 Zone storage complex. With most of the North Belridge oil field 64 Zone development occurring before the 1970s (**Figure 2.4-13**), modern wireline log data are scarce and generally representative of a depleted 64 Zone reservoir.

Several conventional cores were acquired during early phases of field development in the 1930s and 1940s; however, few cores were sampled for laboratory analysis of reservoir properties. Three of those cores exhibited good recovery through the 64 Zone W Sandstone, and routine core analyses were conducted from the following cores: 4-36N, 7-1N, and 8-1N (later renamed as 511-1N). In the 1980s, three conventional cores in the 64 Zone U and W Sandstones were acquired as part of a large reservoir evaluation conducted by Shell California Production Inc.: 17-2N, 43-27N, and 4-1N. The locations of wells with conventional core data are shown in **Figure 2.4-14**. Hole conditions caused by pressure depletion negatively impacted core recovery and wireline logs. As a result, continuous modern wireline logs and core recovered through the 64 Zone Sandstones are not available in the same wells. Well 17-2N reported the best core recovery, while 43-27N had the highest-quality wireline logs (**Figure 2.4-15**).

The six cored wells described in the previous paragraph contribute a total of 1,170 samples with analysis data, of which 1,011 are from the proposed injection zone: 72 and 939 from the 64 Zone U and W Sandstones, respectively (**Table 2.4-3**; **Figure 2.4-16**; **Appendix 2D**).

Although uncertainty is introduced to porosity and permeability measurements by the vintage of the 4-36N, 7-1N, and 511N-1 cores, their nearly complete vertical coverage of the W Sandstone section supplements the dataset, mitigating the poor recovery experienced in the upper W Sandstone in more recent cores. The W Sandstones have been identified in previous studies as the

interval with highest porosity and permeability in the proposed CO_2 storage complex (Kaczorowski et al. 1986) and confirmed by observations in the more recent cores.

In 2011, Aera drilled the deep exploratory well 888N-12, located between the North and South Belridge oil fields (**Figure 2.4-17**), with a total depth (TD) in the Point of Rocks Member of the Kreyenhagen Formation. Among multiple conventional cores, 80 ft of continuous core was recovered from the Upper Santos Shale, in an area where the Agua Sandstone is thin. Routine core analysis was performed on 64 samples taken from the Upper Santos Shale interval in this core (**Table 2.4-3** and **Figure 2.4-16**), providing direct measurements of porosity, grain density, and permeability to air of the confining zone formation.

As described in detail in **Section 2.4.2.2**, the Lower Santos Shale is a generally massively bedded medium to dark-gray and brown claystone with very little silt or sand with few intervals of hard, platy siliceous shale, and platy to blocky calcareous shale (Carter 1985). The Upper Santos Shale comprises two general facies: dark gray to brown clay shale with thin-silt and sand-interbedded laminations, and tan, platy, siliceous and calcareous clay shales (Carter 1985; Foss and Blaisdell 1968). Because the two units are broadly similar, petrophysical properties developed from conventional core analyses of the Upper Santos Shale are also applied to the Lower Santos Shale in the storage complex simulation model. Because the Upper Santos Shale generally contains greater silt and sand components relative to the Lower Santos Shale (Foss and Blaisdell 1968; Carter 1985), this assumption is understood to be conservative for the purposes of evaluating the sealing capacity of the primary confining zone. Results of conventional core analyses from the Upper Santos Shale presented in tables and figures in this section are thus denoted simply as "Santos Shale" because they are taken as representative of both shale units of the Santos Shale Member.

Routine core analyses were also performed for samples collected from additional core intervals (including Temblor Sands, Carneros Sandstones, Agua Sandstone, and Oceanic Sandstone) and/or additional core locations (including 1B-21N, 2R-27N, and 50X-27N [**Figures 2.4-14** and **2.4-16**]), for a grand total of 1,310 core samples (**Table 2.4-3**).

Other exploratory wells with modern log suites have been drilled through the confining and injection zones near the North Belridge oil field (**Figure 2.4-17**). Such wells, although not located in the field, are considered key to the characterization effort due to the advanced log suites that were acquired in them (including elemental capture spectroscopy, nuclear magnetic resonance [NMR], dipole sonic, microresistivity image, among others) with continuous coverage of the injection and confining zones. The most data-rich of such wells are the already mentioned 888N-12 (located approximately 1 mile south of the North Belridge oil field boundary, near the southern end of the AoR) and Gump Trust 30-1 (located in the Beer Nose oil field approximately 8 miles to the northwest of the North Belridge oil field and the AoR).

As outlined in the Pre-Operational Testing Plan (**Attachment D**), Aera will attempt the acquisition of rotary sidewall cores during drilling of new injection wells to validate observations made from core acquired in vintage wells. Rotary sidewall cores are preferred over percussion sidewall cores because of their suitability for porosity and permeability measurements. However, recovery of

rotary sidewall cores can be challenging, especially considering the extent of pressure depletion in the 64 Zone Sandstones. The initial plan is to collect up to 50 plug samples per well, which would be evenly distributed through the Lower Santos Shale (primary confining zone) and the 64 Zone Sandstone (injection zone) intervals to confirm observations on vertical heterogeneity. A percussion sidewall coring tool will be available as backup to collect up to 30 samples if rotary sidewall recovery is not satisfactory. Percussion sidewall cores are not suitable for porosity and permeability measurements, but mineralogy and lithology analyses can be performed.

Routine core analysis will be performed on rotary sidewall core samples of sufficient dimensions, which includes porosity measurements via the Boyle's Helium expansion method. A subset of the samples collected from the injection zone (up to five) will be selected in each new well to perform stressed porosity and permeability measurements. A similar number of samples will be selected from the confining layer to perform tight rock analysis (TRA) measurements, including crushed-rock porosity and permeability measurements. If sufficient core material is recovered, additional capillary pressure measurements can also be performed in a subset of the samples, especially for the primary confining unit (Lower Santos Shale) samples. In case rotary sidewall core recovery is not satisfactory, bulk and grain density measurements will be conducted on percussion core plugs or recovered rotary sidewall core material. The specific depths of the samples selected for the special core analysis described above will be selected using well logs with the intent to capture vertical heterogeneity.

2.4.3.1 Porosity (φ)

Defined as the unitless ratio of pore volume to bulk volume of rock (v/v), porosity is a critical reservoir property with direct implications to the storage capacity of the injection zone. Porosity was measured on 1,010 samples from the 64 Zone Sandstones (72 and 938 samples from the U and W Sandstones, respectively) and 64 samples from the Upper Santos Shale by either Archimedes principle or Boyle's law method.

Sedimentary rocks tend to exhibit a general trend of decreasing porosity with increasing depth due to compaction (with deviations from such trend possible due to diagenetic alterations); therefore, variability in the average porosity is expected. The conventional cores available are representative of the depth range (7,894 to 9,141 ft MD) where the 64 Zone Sandstones are encountered in the North Belridge anticline.

Conventional core data exhibit mean (arithmetic) porosity values of approximately 0.07, 0.11, and 0.15 v/v for the Upper Santos Shale, U, and W Sandstones, respectively (**Table 2.4-4**). Larger variability is observed in data from the Upper Santos Shale and the more heterogenous U Sandstone (**Figure 2.4-18**). Log-derived porosity was used to further understand variability of porosity in the 64 Zone Sandstones and Santos Shale. Unfortunately, borehole washouts are common in the few wells with density logs, significantly impacting log quality. Neutron logs are slightly less affected than density logs by borehole rugosity, but their hydrogen index measurement can be affected by the presence of clay minerals and free gas. A density-neutron crossplot porosity (ϕ_{D-N}) was computed as an estimate of total porosity (ϕ_{Total}) in the U and W Sandstones and the Santos Shale. The

density-neutron crossplot porosity accounts for the effects of mineralogy and fluid saturation on log measurements:

$$\phi_{Total} = \phi_{D-N} = \sqrt{\frac{\phi_{density}^2 + \phi_{neutron}^2}{2}};$$

where density porosity ($\phi_{density}$) was computed assuming a fluid density of 1 gram per cubic centimeter (g/cm^3) and using the average (arithmetic mean) grain density values observed from core of 2.65 g/cm^3 for the U Sandstone and the Upper Santos Shale, and 2.63 g/cm^3 for the W Sandstone (**Figure 2.4-19**). Neutron porosity ($\phi_{neutron}$) is a direct log measurement.

Figure 2.4-20 presents the distribution of log-derived total porosity from 11 wells, displaying wider distributions than core data, particularly for units other than the W Sandstone. The log data also appear to capture the higher porosity values (in excess of 0.15 v/v) commonly observed in the upper W Sandstone. **Table 2.4-5** contains the respective summary statistics for log-derived porosity, also reflecting the wider distributions of porosity for both 64 Zone U and W Sandstones observed from log data. The mean value of log-derived porosity is around 0.13 v/v for both the U and W Sandstones (slightly higher than the 0.11 v/v and lower than the 0.15 v/v observed from core for the U and W Sandstones, respectively). It is important to note that the volume of investigation of log measurements is larger than that of core analysis. Also, log measurements are expected to yield a total porosity measurement at reservoir conditions, as compared to core measurements, which are conducted at ambient conditions. The U Shale and Lower Santos Shale reported a mean value of log-derived total porosity of 0.08 v/v, exhibiting much larger variability than the sandstone reservoirs. The shale intervals were observed to be particularly affected by borehole washouts, so only values from in-gauge hole were used to compute statistics.

Porosity measurements from routine core analyses were performed at atmospheric conditions and are not representative of reservoir conditions. Special core analyses for the 17-2N core included porosity measurements at simulated original reservoir conditions (confining stress of 3,700 psi) in eight samples. A comparison of unstressed and stressed porosity values is presented in **Figure 2.4-21** (note: two of the eight samples plot exactly on top of each other). Reported stressed porosity values (at simulated reservoir conditions) are between 0.004 and 0.007 v/v lower than their corresponding measurements at ambient conditions, with the exception of a sample in the lower W Sandstone with a difference of 0.017 v/v. A previous study reported correction factors of 0.01 v/v for low-quality reservoir rocks and 0.005 v/v for high-quality reservoir rocks (Kaczorowski et al. 1986).

Several direct comparisons of the log-derived porosity data with porosity measured in core have been made. Where there are good quality modern logs, the core data support the log derived data. Modern logging suites, including density and neutron porosity logs, were collected in the three wells with conventional core taken from the 64 Zone Sandstones in the 1980s (17-2N, 43-27N, and 4-1N). However, borehole rugosity was a prevalent issue, compromising log data quality in cored intervals. In well 17-2N, continuous core was recovered from the bottom 60 ft of the U Sandstone and almost the entire W Sandstone interval; however, porosity logs were only run in the W Sandstone interval, and due to the pervasive borehole washouts, density log measurements

are not usable in the top 120 ft of that sandstone member (see 17-2N log layout in **Figure 2.4-22**), allowing for partial comparison of core- and log-derived porosity in that well. Stressed porosity data are available for 14 samples from well 17-2N subjected to mercury-injection capillary pressure and electrical properties measurements; however, only five samples come from depths with porosity logs not significantly affected by borehole rugosity. A few short cores were recovered from well 43-27N: approximately 20 ft in the U Sandstone, 3 ft from the upper W Sandstone, and approximately 25 ft from the lower W Sandstone (see 43-27N log layout in **Figure 2.4-22**). Borehole integrity was much better in this well, resulting in better quality porosity log data that allow for comparison to core measurements. In 2012, rotary sidewall cores were recovered from the 64 Zone Sandstones in well 888N-12 (one and 11 sidewall cores from the U and W Sandstones, respectively). Borehole condition was conducive to acquiring density, neutron, and NMR logs, providing three independent measurements to estimate porosity (see 888N-12 log layout in **Figure 2.4-22**). There is generally a good visual correspondence between the computed density-neutron crossplot porosity and unstressed core porosity measurements (**Figure 2.4-22**). Conventional core in the U Sandstone and NMR logs through the U and W Sandstone intervals were also acquired in off-site (outside of AoI) well Gump Trust 30-1 (**Figure 2.4-22**).

A crossplot of core porosity versus log-derived total porosity (**Figure 2.4-23**) shows that the W Sandstone core porosity (most samples are from 17-2N) is on average 2 to 3 porosity units higher than the log-derived total porosity. It is important to note that core porosity measurements in the crossplot are unstressed. As indicated above, the previous study (Kaczorowski et al. 1986) found stressed porosity to be 0.5 to 1 porosity units lower than unstressed porosity. The larger difference between the log-derived and core porosities may be explained by the presence of free gas affecting the crossplot porosity computation. A crossplot comparing log-derived total porosity data with the five stressed porosity measurements on 17-2N samples (**Figure 2.4-24**) displays what appears to be a better agreement in the samples with porosity above 10 porosity units. In contrast, the log-derived total porosity estimates for the U Sandstone (primarily from the Gump Trust 30-1 well) appear to be generally higher than the unstressed porosity measurements by an average of 1 to 2 porosity units, driven by higher neutron porosity values potentially caused by the presence of clay minerals. It is also important to note that core and log measurements have significantly different volumes of investigation (much larger for log measurements), which in the presence of reservoir heterogeneity can explain the lack of agreement between measurements.

There has not been a systematic attempt to convert total porosity to effective porosity due to the lack of a calibration dataset for effective porosity. The term effective porosity is of widespread use, but its definition is somewhat subjective. Herein, the log analysis definition of effective porosity proposed by Hook (2003) has been adopted, which excludes clay-bound water (not accessible to other fluids at reservoir conditions) from pore volume but includes capillary bound water (which depends not only on rock properties but also on column height). Both neutron and density log measurements respond to the total pore volume in the near wellbore region (as a function of electron density or hydrogen index). Core porosity via gas expansion or re-saturation is an effective porosity measurement in the sense that it measures the connected fraction of the bulk rock volume. However, the amount of retained clay-bound water depends on sample preparation, particularly the drying technique (Hook 2003). For oven-dried samples, the

measurement will be close to total porosity, while in humidity-controlled drying it is uncertain whether results are representative of reservoir conditions. Therefore, a core-based calibration dataset for effective porosity derived from logs is not available. However, considering the low clay content measured in the 64 Zone Sandstones (**Section 2.8.2.1**), it is expected that total and effective porosity will be similar.

NMR logs respond to the abundance of hydrogen atoms in pore fluids, providing a measurement of total porosity relatively insensitive to lithology. Historically, T2 relaxation times of less than 3 milliseconds have been associated with clay-bound water, so removing that portion of the total pore volume can lead to an estimate of effective porosity (Coates et al. 1997). A crossplot of NMR estimates for total and effective porosity was generated using data from the 888N-12 and Gump Trust 30-1 wells near the North Belridge oil field, showing that estimates of effective porosity are 1 to 2 porosity units lower than total porosity for the U and W Sandstones and 5 to 8 porosity units lower for the Lower Santos Shale and U Shale (**Figure 2.4-25**). It should be noted that NMR porosity estimates are sensitive to borehole rugosity, free gas saturation, and operating parameters (logging speed).

Overall, the existing dataset provides sufficient information to characterize porosity in the 64 Zone U and W Sandstones. Additionally, in the Pre-Operational Testing Plan (**Attachment D**), Aera has included the intent to acquire continuous wireline porosity logs and rotary sidewall core samples from the newly drilled and repurposed injection wells to confirm observations made regarding porosity trends. Aera also intends to acquire NMR logs to provide another independent porosity measurement if borehole conditions are suitable. As mentioned above (**Section 2.4.3**), routine core analysis performed on rotary sidewall core samples of sufficient dimensions includes porosity measurements via the Boyle's helium expansion method. A subset of the samples collected from the injection zone (up to five) will be selected in each new well to perform stressed porosity measurements and a similar number of samples will be selected from the confining layer to perform TRA measurements, including crushed-rock porosity measurements. In case rotary sidewall core recovery is not satisfactory, bulk and grain density measurements will be conducted on percussion core plugs or recovered rotary sidewall core material.

2.4.3.2 Permeability (k)

In addition to porosity, permeability is another key property of both the injection and confining zones. Permeability controls the ability and rate at which CO_2 can be injected and determines the suitability of the confining zone to keep injected volumes from migrating upwards. As was the case with porosity, the conventional core analysis data acquired in the North Belridge oil field throughout its history provide a useful dataset to understand trends in permeability for both the U and W Sandstones. Data from conventional core acquired in the 1940s (7-1N, 511-1N and 4-36N) and the 1980s (17-2N, 4-1N, 43-27N) were used to compute sample statistics, exhibiting good vertical coverage of the 64 Zone W Sandstone. Core data collected from the Upper Santos Shale in well 888N-12 was used to provide insights for permeability of the confining zone.

Intrinsic (absolute) permeability to air was measured on 1,066 horizontal plugs from the Upper Santos Shale and the U and W Sandstones from seven cores, which includes most of the samples subjected to total porosity measurements. Probability density plots and summary statistics of the

64 Zone Sandstones are presented in **Figure 2.4-26** and **Table 2.4-6**. There is a clear difference in the empirical distributions of absolute permeability to air measured on samples from the 64 Zone U and W Sandstones. Values in the U Sandstone generally vary in the 0.1 to 10 millidarcy (mD) range, with a median around 1 mD; whereas, in the W Sandstone, permeability can vary in the 1 to 150 mD range, with a median value around 29 mD and values as high as 400 mD. A log layout of well 17-2N, including routine core analysis data, clearly displays significant vertical variability in absolute permeability to air through the 64 Zone W Sandstone (**Figure 2.4-27**), with dramatically different average permeability in the upper and lower portions of the W Sandstone. In addition, the lower permeability observed from core analysis data in well 17-2N around 8,560 ft and 8,700 ft appears to correlate with slightly lower porosity values. Core descriptions indicate observed calcite cementation at 8,566.7 ft and 8,692.2 ft (**Appendix 2D**). NMR logs in well 888N-12 (discussed further below in this section) show multiple thin spikes of low Timur-Coates and Schlumberger-Doll Research permeability values (around 9,200 ft; 9,252 ft; and 9,348 ft), correlating with indication of calcite from the ECS logs. Such calcite-cemented intervals could have an impact on vertical (or lateral) fluid migration only if laterally continuous.

Many of the air permeability measurements performed on the plugs extracted from the Upper Santos Shale core reported values below the lower limit of routine (steady state) analysis methods. This indicates a very low matrix permeability in the Upper Santos Shale. One pressure decay measurement on crushed rock (unsteady-state method), which is more suitable to tight rocks, was made in 2012 from the 888N-12 core, yielding a value of 0.00014 mD (140 nanodarcies [nD]). An additional three pressure decay permeability measurements were performed on the Upper Santos Shale samples from the 888N-12 core in 2023, yielding a range of estimates from 0.000046 to 0.000114 mD (46 to 114 nD), which is four to six orders of magnitude lower than the permeability measured in the W Sandstone.

Air permeability correlations were used to generate the geocellular model permeability property (**Section 2.2.2** and **Appendix 2B**), which was used as an input to the reservoir simulation model (described in **Attachment B**). Geomodel permeability values within the W Sandstone were calculated based on a function (permeability prediction algorithm) utilizing estimated porosity curves from wells with valid porosity log data and depth below the top of the W Sandstone surface. This function is calibrated to core permeability measurements; however, the limited vertical resolution of the calcite cemented intervals (discussed above for the W Sandstone in well 17-2N), as well as the lack of presence in other wells used to calibrate the model, resulted in little-to-no representation in the geomodel at the 17-2N well location. Larger-scale permeability trends, which will have a more significant effect on simulation and fluid flow, are observed throughout the W Sandstone and other permeable layers within the geomodel (see **Appendix 2B**). Within these larger-scale features, fluid migration is anticipated to follow high permeability streaks, manifesting as preferential lateral fluid flow in the upper W Sandstone where permeabilities are higher.

As was the case with porosity, absolute permeability measured in the laboratory reflects ambient conditions. In addition to correcting for the effect of confining stress, absolute permeability to air can be converted to permeability to the liquid phase encountered in the reservoir. Even though data from measurements of stressed permeability to brine have not been located at this time, Shell

California Production Inc. reported to have conducted measurements for 30 samples from the 17 2N and 4-1N cores (Kaczorowski et al. 1986), proposing empirical correlations of the form:

$$k_{brine,stressed} = c * k_{air,unstressed}$$

With a constant c = 0.305 for the higher-quality reservoir facies encountered in the upper portion of the 64 Zone W Sandstone. Alternatively, relative permeability functions can be used to account for reservoir conditions in the modeling effort. The information herein was presented to inform the site characterization effort; however, neither the empirical correlation obtained by Shell California Production, Inc., nor the relative permeability functions, were used to transform the air permeametry values into formation fluid permeability for use in the geomodel. The geomodel is a 3D representation of air permeability values, as discussed in **Appendix 2B**.

NMR logs can be used to make empirical estimates of absolute permeability because they are sensitive to liquid-filled porosity and pore size distribution by exciting hydrogen nuclei in the pore fluid, inducing a magnetic field. **Figure 2.4-28** presents a log layout of the injection and confining layers in the two key recent offset wells with NMR logs: 888N-12 and Gump Trust 30-1 (locations shown on **Figure 2.4-17**). Only data from intervals of relatively good log quality are displayed in the log layouts and probability density plots and are used for generating summary statistics. Both the density plot (**Figure 2.4-29**) and summary statistics (**Table 2.4-7**) display a marked difference in NMR Timur-Coates permeability between the U and W Sandstones and the shales (Lower Santos Shale and U Shale). The median permeability values in the Lower Santos Shale and the 64 Zone W Sandstone are 0.02 mD and 1.8 mD, respectively, which is a difference of two orders of magnitude.

Timur-Coates and Schlumberger-Doll Research empirical permeability calculations exhibit good agreement with core permeability measurements (Timur 1968; Chang et al. 1994); however, discrepancies are expected due to differences in volume of investigation and experimental conditions (reservoir conditions for NMR logs versus laboratory conditions for core analysis). NMR logs are a relatively shallow measurement, and as a result, are highly sensitive to borehole washouts, which unfortunately are a common occurrence in the Santos Shale in the 888N-12 well. Without having NMR core data, no attempt has been made to calibrate NMR permeability estimates to core data due to the lack of a calibration dataset. Thus, NMR permeability estimates presented herein were used for comparison to core measurements and are used for discussion of vertical heterogeneity of permeability.

As presented on **Figure 2.4-28**, there is generally a good correspondence in trends of core permeability to air and NMR Timur-Coates permeability estimates, especially for the W Sandstone rotary sidewall cores from 888N-12 (**Figure 2.4-30**). A crossplot of core permeability to air and depth-shifted NMR Timur-Coates estimates shows positive correlation but significant dispersion around the one-to-one line (**Figure 2.4-31**). Timur-Coates permeability is generally higher than core measurements of permeability to air for the U Sandstone data from well Gump Trust 30-1. For most of the rotary sidewall cores from well 888N-12, Timur-Coates permeability appears to overestimate core permeability. However, the observation of NMR porosity potentially

underestimating total porosity may imply sufficient polarization was not achieved, thus affecting the permeability estimates as well.

It should be noted that core permeability was measured with air at ambient conditions, whereas NMR logging is a downhole measurement. However, it is also important to note that the Timur-Coates permeability estimation is empirical and relies on a formation-specific constant and the ratio of free fluid to bound fluid, which is based on the selection of a T2 relaxation time cutoff that is generally set to 33 milliseconds for sandstones but can also vary by formation. Calibration of NMR Timur-Coates estimates to reservoir conditions will be pursued if Aera can successfully acquire NMR logs and core data through the proposed CO_2 storage complex in new wells.

At the very low permeabilities (nD range) observed in pressure-decay measurements for four Upper Santos Shale samples from well 888N-12, log-derived methods such as Timur-Coates estimates are not expected to be valid (Wang et al. 2021). For that reason, and because of the presence of borehole washouts in the Upper Santos Shale interval of well 888N-12, no comparison between core measurements and log estimates was possible in the confining unit.

Overall, the existing dataset provides sufficient information to conclude that, apart from the presence of a few calcite-cemented intervals with lower permeability, there appears to be some extent of permeability degradation at the base of the 64 Zone W Sandstone. Additionally, in the Pre-Operational Testing Plan (**Attachment D**), Aera has included the intent to acquire NMR logs and rotary sidewall core samples from the newly drilled injection wells to confirm observations made regarding permeability trends. As mentioned above (**Section 2.4.3**), a subset of the samples collected from the confining layer (up to five) will be selected in each new well to perform TRA measurements, including crushed-rock permeability measurements. If borehole conditions are suitable, NMR logs will be acquired to provide a vertically continuous estimate of permeability in the AoR and another independent permeability measurement. It is important to note that NMR logs have a small radius of investigation and are extremely sensitive to borehole rugosity. Aera will also plan for NMR porosity measurements on core for calibration purposes if rotary sidewall cores are successfully recovered. If the attempts to acquire rotary sidewall cores and modern log suites (including NMR) in new injection wells are successful, newly acquired data will be used to first validate the permeability prediction algorithm (mentioned above and described in more detail in **Appendix 2B**); if significant discrepancies are observed, the algorithms will be refined with the newly acquired data.

2.4.3.3 Capillary Pressure (P_C)

Capillary pressure measurements provide information on the distribution of pore throat size and how fluids occupy the pore space under the balance of buoyancy and capillary forces. That information is critical to understanding how CO_2 penetrates the injection zone and the ability of the confining zone to impede leakage.

The conventional cores of the injection zone (64 Zone U and W Sandstones), including 7-1N, 511-1N, 4-36N, 17-2N, 4-1N, and 43-27N, provide the dataset used in this section to describe reservoir properties. Mercury-injection capillary pressure was measured in 27 samples from the 17-2N, 4-1N, and 43-27N cores: five from the U Sandstone and 22 from the W Sandstone at the

time of acquisition (1980s [Kaczorowski et al. 1986]). At present day, only a subset of the tabular capillary pressure data is available in digital format along with their corresponding porosity and permeability values, which includes 15 capillary pressure curves from 17-2N. Additionally, capillary pressure curves are available for three sidewall cores from well 23-1N; however, due to the nature of percussion sidewall coring, which can potentially alter the pore system, those measurements should be used with caution. Mercury-injection capillary pressure measurements were also performed on five plugs extracted from the Upper Santos Shale core in well 888N-12, which were used due to their relevance to the confining zone.

A plot of the mercury/air capillary pressure curves available in digital format of the samples from the 64 Zone Sandstones and Upper Santos Shale exhibits markedly different entry pressures and curve shapes (**Figure 2.4-32 inset a**). Mercury entry pressures vary in the 5 to 60 pounds per square inch absolute (psia) range for the U and W Sandstones, with lower values corresponding to higher-permeability samples (**Figure 2.4-32 inset b**). Mercury entry pressures vary between 2,500 and 7,950 psia for the Upper Santos Shale samples. Similar results were reported in a previous evaluation using the capillary pressure collected at the time, with entry pressure ranging between 9 and 70 psia for the U and W Sandstones, inversely correlated with average porosity and permeability (Taylor 1987). It is generally expected that higher permeability rocks will contain larger pores and that the non-wetting fluid (mercury in laboratory conditions) can enter at lower injection pressures. Pore throat radius (r) can be computed from capillary pressure as:

$$r = \frac{2\sigma\cos(\theta)}{P_C};$$

where Pc is the capillary pressure at any non-wetting phase saturation, while σ and θ are the interfacial tension and contact angle of wetting and non-wetting phase (mercury/air in laboratory conditions), respectively. Empirical pore throat size distributions were computed from each available capillary pressure curve using the following assumptions, as reported in Purcell (1949):

$$\sigma_{Hg/Air} = 480\ dyne/centimeter$$

$$\theta_{Hg/Air} = 140\ degrees$$

The largest pore throats within the 64 Zone Sandstones vary in size between 1 and 10 micrometers, while they are generally smaller than 0.02 µm for the Upper Santos Shale samples (**Figure 2.4-33 inset a**). Pore throat size generally increases with permeability (**Figure 2.4-33 inset b**).

Mercury injection capillary pressure testing results available in digital format were converted to CO_2/brine equivalents using the following assumptions, as reported in Lohr and Hackley (2018):

$$\sigma_{CO2/Brine} = 25\ dyne/centimeter$$

$$\theta_{CO2/Brine} = 70\ degrees$$

As noted on the mercury/air plots, the CO_2/brine capillary pressure curves of the samples from the 64 Zone Sandstones and Upper Santos Shale exhibit markedly different entry pressures and curve shapes (**Figure 2.4-34 inset a**), with lower entry pressure values corresponding to higher-permeability samples (**Figure 2.4-34 inset b**).

As discussed in the Pre-Operational Testing Plan (**Attachment D**) and in **Section 2.4.3** above, Aera has included the intent to acquire rotary sidewall core samples from the newly drilled injection wells to confirm observations made from core acquired in vintage wells. If sufficient core material is recovered, it is expected that additional capillary pressure measurements can be performed in a subset of the samples, especially those from the primary confining unit (Lower Santos Shale).

2.4.4 Injectivity, Storage Capacity, and Integrity

2.4.4.1 Injectivity

The injectivity of the proposed storage complex is demonstrated experientially by the long history of production and injection of the 64 Zone Sandstones and quantitatively by historical multipoint gas injection tests. As described in detail in **Section 2.10.1**, a discretized wellbore PROSPER model was built to match the gas test results and calibrate the model to the reservoir and well conditions before running predictions and sensitivities for CO_2 injection modeling. Results of the well injectivity sensitivity based on two permeability models estimate between 2,000 to 5,000 tonnes/day injection capacity, with an imposed adaptive 80% of fracture pressure limitation under reservoir re-pressurization, as required by 40 CFR 146.88 (a). These results indicate 64 Zone injectivity is sufficient to support CO_2 injection, given proper sizing of the tubing, manageable well skin, sufficient pressure differential with the reservoir, surface control, and pressure monitoring.

2.4.4.2 Storage Capacity

CO_2 storage capacity in the 64 Zone was estimated using the Oil and Natural Gas Reservoirs Production Method, as described in detail in **Section 2.10.3**, and summarized in **Table 2.10-1**. The method converts surface volumes of produced oil and gas to subsurface CO_2 volumes on a volume-for-volume basis. A high estimate of potential CO_2 storage capacity, based on the cumulative production of hydrocarbons (oil and gas), is 42.6 MM mt of CO_2. A low estimate of potential CO_2 storage capacity is 22.9 MM mt of CO_2, which is calculated with a material balance approach focused on recovery of free gas from the reservoir's gas cap—the most accessible storage target. A mid-range estimate at 32.7 MM mt of CO_2 storage capacity is proposed using an average of the low and high range estimates.

The injection zone is a depleted oil and gas reservoir; therefore, the storage efficiency was not utilized in the storage capacity calculations. The sequestered CO_2 is modeled to primarily occupy the original free gas cap of the oil and gas reservoir. Consequently, the primary factor in estimating storage capacity was the pore volume of the withdrawn gas and fluids from the reservoir and not the storage efficiency of the water leg.

As discussed in the Pre-Operational Well Testing Plan (**Attachment D**), the AoR model will be updated and refined as data are gathered. As mentioned above, initial estimates of storage capacity were performed using material balance methods, as complements to the model-derived estimates presented in **Attachment B**. Subsequent storage capacity estimates have been performed using a refined simulation model derived from a geologic model that incorporates existing seismic data,

well tops, and petrophysical data from both core and well logs. These models will be supplemented and updated with well tops and petrophysical data gathered during well construction. New well tops will help to refine the top and base of the injection zone. Newly acquired petrophysical data will supplement the existing database to better inform reservoir properties, such as porosity and permeability, that affect storage capacity. In addition, leak-off tests will be performed during well construction to better refine the fracture gradient, which dictates the maximum injection pressure for each well in the project and, consequently, impacts the storage capacity. Once these data are incorporated into the existing model, additional simulation runs will be used to further constrain the storage capacity.

2.4.4.3 Integrity

The data related to integrity of the proposed CO_2 storage complex are analyzed in detail in **Sections 2.3** and **2.5**, and a detailed discussion of the confinement of the proposed storage complex is presented in **Section 2.10.2**. Fracture data sets from two wells within the AoI indicate that the primary confining zone is only very slightly fractured and the injection zone is effectively unfractured. Consequently, fractures are expected to have a negligible influence on the sealing capacity of the primary confining zone and the transmissivity of the injection zone. Static pressure measurements collected from the 64 Zone Sandstones were utilized to demonstrate that bounding faults of the AoR create compartmentalization and serve as barriers to flow out of the injection zone. Mechanical integrity analysis of the caprock indicates that the stress state in the Lower Santos Shale is below the Mohr Coulomb shear failure envelope, assuming the formation has zero cohesive strength and with frictional angle of 31º. A pore pressure increase of 741 psi, and a post-injection pore pressure increase of 379 psi, is required to move the Lower Santos Shale stress state into a critically stressed condition from the current static state. Given the elevated confining zone entry pressure and the low permeability, the anticipated maximum differential pressure at the base of the confining zone under the proposed operating condition is expected to be close to zero. These results suggest that within the model constraints the confining zone is stable without risk for shear failure.

2.5 Geomechanical Characterization [40 CFR 146.82(a)(3)(iv)]

The geomechanical characterization provides the basis to accomplish the following:

- Evaluate the injection and confining zone fracture gradients to determine safe injection and storage pressures.
- Evaluate the ductility of the primary and secondary confining zones for the storage complex.
- Evaluate fault seal and fault stability at injection operations and storage conditions.
- Demonstrate confining zone integrity and, thus, its capacity to be a seal to injection fluids (**Section 2.10**).

A one-dimensional Mechanical Earth Model (1D MEM) was developed for the 13 modelled horizons that comprise the 3D static geologic model using modern log suites, including density and dipole sonic logs, from well 888N-12 (**Figure 2.5-1**). Well 888N-12 is located about a half a

mile southeast of the storage complex (**Figure 2.2-1**). Log-based properties were calibrated with rock mechanics testing of existing core samples of the 64 Zone W Sandstone from wells 17-2N and 4-1N and samples of the Upper Santos Shale from well 888N-12.

Rock mechanics analyses performed included indirect tensile strength, unconfined compressive strength (UCS), triaxial compression, multiple stress-path compression, and ultrasonic velocity tests of 16 core samples of the 64 Zone W Sandstone across four depth intervals and 18 samples of the Upper Santos Shale across three depth intervals. A summary of core sample properties and test results is provided in **Table 2.5-1**. Mohr-Coulomb diagrams summarizing the results of triaxial compression testing, including calculated values for friction angle and cohesion, are provided on **Figure 2.5-2** and **Figure 2.5-3**.

Average strength and static elastic properties were calculated for each core interval to calibrate log-based estimates of rock properties. Average UCS was calculated from direct test results and Mohr-Coulomb estimates from triaxial testing. Friction angle and cohesion were calculated using best fit Mohr-Coulomb failure envelopes. In samples of the 64 Zone W Sandstone, Young's Modulus and Poisson's Ratio did not vary significantly at confining pressures above 3,800 psi, and average values were calculated using logarithmic regression. In samples of the Upper Santos Shale, Young's Modulus increased with confining pressure across all test conditions and, thus, maximum values were selected for log calibration. In contrast, Poisson's Ratio did not show a clear correlation with confining pressure in samples of the Upper Santos Shale, so minimum values were selected for log calibration.

Log-based estimates of rock properties were calibrated with average values from core analyses of the 64 Zone W Sandstone and Upper Santos Shale (with core results from the 64 Zone W Sandstone depth-shifted to their corresponding depth on 888N-12 logs). UCS and friction angle were estimated using empirical correlations (Chang, Zoback, and Khaksar 2006). Dynamic elastic properties, including Young's Modulus and Poisson's Ratio, were computed based on the bulk density, compressional, and shear slowness measured with open-hole wireline logs and empirically correlated to the corresponding values for static elastic properties. Young's Modulus is frequency dependent; therefore, estimates from log measurements must be transformed into static conditions. The dynamic Young's Modulus was transformed into the static Young's Modulus using empirical correlations for the 64 Zone W Sandstone (Equation 1) and Upper Santos Shale (Equation 2) calibrated to the average static Young's Modulus values calculated from core measurements. The static Poisson's Ratio is assumed to be equal to the dynamic Poisson's Ratio multiplied by an empirically derived multiplier: 1.0 for the 64 Zone W Sandstone and 0.85 for the Upper Santos Shale.

Equation 1:

$$E_{static} = 0.01 \times E_{dynamic}^{2.16} \; [GPa]$$

Equation 2:

$$E_{static} = 1.2 \times E_{dynamic}^{0.85} \; [GPa]$$

The characterization of the in-situ stress field consists of the quantification of magnitude and orientation of its three components: vertical stress (S_V), minimum horizontal stress (S_{HMIN}), and maximum horizontal stress (S_{HMAX}). S_V was determined by integrating the density logs (**Figure 2.5-1**) with depth. S_{HMIN} and S_{HMAX} were estimated using the poroelastic horizontal strain model, which assumes that the rocks are a semi-infinite poroelastic medium subjected to overburden and horizontal strain loadings (Higgins et al. 2008).

S_{HMAX} was obtained by modeling the borehole breakout features (Zoback et al. 2003) and found to be consistent with a strike-slip stress regime ($S_{HMAX} > S_V > S_{HMIN}$), as indicated from a recent study of the North America crustal stress field (Lund Snee and Zoback 2020). The orientation of S_{HMAX} of N29 ± 15°E was determined from the borehole image logs from well 888N-12 on borehole breakout (**Figure 2.5-4**) and corroborated by the Fast Shear Azimuth calculated from the dipole sonic log of the same borehole. This is consistent with the world stress map (https://www.world-stress-map.org/) and a study from Chanchani et al. (2003) in the Buena Vista Hills field in the southern San Joaquin Valley.

The S_{HMIN} profile was constrained by leak-off test data from the shallower interval in the Temblor Sands of the Monterey Fm and diagnostic fracture injection test data from the deeper intervals in the Kreyenhagen Shale and Point of Rocks Sandstone Members of the Kreyenhagen Fm in well 888N-12. Pore pressure (PP) for well 888N-12 was estimated using the drilling mud weight, constrained by kick events, and formation pressure analysis from Modular Dynamic Tester data (**Figure 2.5-1**). Due to the production history of the field, the state of stress has changed over time. To extrapolate the S_{HMIN} to the initial condition in the 64 Zone U and W Sandstones, the theory of poroelasticity is employed, which describes the change in horizontal stress (ΔSh) as a function of pore pressure (Engelder and Fischer 1994). The ratio of change in horizontal stress to change in pore pressure ΔSh/ΔPP is approximately 0.75 using an average Poisson's Ratio of 0.2 and a Biot coefficient of stress (α) of approximately 1. The change in the S_{HMIN} over time can be analyzed from step-rate tests. These tests can be used to evaluate the stress path of the formation and to guide the maximum injection pressure to prevent the initiation and/or propagation of fractures in the injection and confining zones, as shown in **Figure 2.5-5**. Injection rates and volumes are presented in **Section 7**.

A 3D analytical geomechanical model was developed using the rock properties from the 1D MEM combined with the 3D grid and forecasted pressures from the reservoir simulation model (described in **Section 1.7** of **Attachment B**) to further evaluate the spatial distribution of the stress level changes across the model domain. This 3D model was used to evaluate the induced stresses on the injection zone as well as the primary confining layer (**Table 2.5-2**), the results of which are discussed in detail in **Section 1.7.1** of **Attachment B**. Thermal sensitivity cases were run and are described in detail in **Section 1.7.1** of **Attachment B**; results of the 180 °F case are presented in **Section 2.3.3.2** and **Table 2.5-2.** A summary of the thermal sensitivity cases run over the fault stability analysis for injectate temperatures other than 180˚F is also described in **Section 2.3.3.2.**

2.6 Seismic History [40 CFR 146.82(a)(3)(v)]

The San Joaquin Basin is located on the western margin of the North American Plate, which is bounded to the west by the SAF (**Figure 2.1-2**). The SAF is a northwest-trending right-lateral (dextral) transform fault that marks the tectonic plate boundary between the North American Plate to the east and the Pacific Plate to the west. The SAF accommodates much of the relative plate motion between the North American and Pacific Plates and has an average slip rate of 20 to 35 millimeters per year (mm/year) (Southern California Earthquake Data Center [SCEDC] 2013a). Additional plate motion is accommodated along numerous faults distributed throughout California.

Estimates of earthquake shaking potential prepared by the California Geological Survey (CGS) and United States Geological Survey (USGS) indicate that the AoI/AoR are located within an area of moderate seismic risk. **Figure 2.6-1** presents a map of earthquake shaking potential for the southern San Joaquin Basin and surrounding regions, which depicts the relative intensity of shaking that has a 2% chance of occurrence in 50 years (adapted from Branum et al. 2016). Estimates of earthquake shaking potential are derived from the Uniform California Earthquake Rupture Forecast (Version 3.0; Field et al. 2013), a probabilistic seismic risk model that considers the location and activity of major faults, historical earthquake observations, and amplification effects of near-surface geologic materials. On **Figure 2.6-1**, relative intensity of shaking is represented by a color gradient ranging from green (lowest intensity) through red (moderately high intensity) to pale purple (highest intensity). Within the southwestern San Joaquin Basin, estimated shaking intensity is highest along the SAF and decreases to the northeast with distance from the fault. The AoI is located approximately 21 kilometers (km) (13 miles) northeast of the SAF, in an area of moderate earthquake shaking potential – 2% probability of experiencing a peak ground acceleration of 0.2 to 0.5 standard gravity (g) within 50 years (Branum et al. 2016; Petersen et al. 2008). While earthquake shaking potential is useful as a metric of overall seismic risk, it does not necessarily and adequately characterize the seismic risk of the proposed CO_2 storage complex. Moderate to strong ground shaking may not pose an inherent threat to CO_2 containment capacity (including confining zone integrity, fault sealing properties, and well integrity at the surface or at depth), unless it is accompanied by fault slip within the storage complex.

Evaluating the effects of seismic shaking on the integrity of oil and gas reservoirs and underground storage projects is an area of active and evolving research. Studies of existing wells in seismically active regions have attempted to quantify the risk of well bore leakage due to ground shaking (Kim et al. 2023) or identify high-risk areas where the density of existing wells and probability of strong ground motions are greatest (Kang et al. 2019), but few specific examples of well bore leakage resulting from seismic activity have been identified (Kang et al. 2019; Iyer et al. 2022).

Similarly, while there is evidence that the permeability of active fault zones may be temporarily increased following large slip events, at least in crystalline bedrock terranes (e.g., the 1995 magnitude 7.3 Hyogoken-Nanbu earthquake on the Nojima Fault near Kobe, Japan [Kitagawa et al. 2022]), studies documenting similar effects resulting from seismic shaking without induced slip were not identified. Furthermore, studies of induced seismicity associated with CO_2 injection indicate that fault leakage is unlikely to result from such events due to the high clay content of caprock formations (Vilarrasa and Carrera 2015) and is especially unlikely in thick multi-caprock systems (Rinaldi et al. 2014); both conditions apply to the proposed CO_2 storage complex.

To evaluate whether seismic activity may pose a threat to the containment capacity of the proposed CO_2 storage complex, the location and activity of known regional faults and the locations of historical earthquake epicenters in the vicinity of the AoI were also examined. As documented below, faults with known Quaternary activity and surface rupture were not identified within the AoR or AoI. While there are active faults within the region that have the potential to produce significant shaking, none are expected to induce subsurface ruptures within the AoR. Since 1950, only one earthquake event greater than magnitude 4.0 has been recorded within 15 km of the AoI. Over the same period, only ten events greater than magnitude 2.0 have been recorded within the AoI boundary, with only two of those occurring inside the AoR. The two earthquakes located within the AoR had a magnitude of 2.1 and occurred at a depth between 9 and 20 km (29,529 to 65,620 ft). Given that the average depth of the base of the 64 Zone W Sandstone is approximately 9,100 ft bgs within the geologic model domain, these earthquakes could not have been associated with fault slip at depths equivalent to the proposed CO_2 storage complex. Based on these observations, Aera believes it is unlikely that shaking resulting from an earthquake on the SAF or another known fault would induce slip on the pre-Quaternary inactive faults within the AoR or result in a release of CO_2 from the storage complex.

2.6.1 Regional Fault Activity

Significant faults with known Quaternary activity and surface rupture have not been identified within the AoI. A fault activity map for the southern San Joaquin Basin and surrounding regions is presented on **Figure 2.6-2**. Major faults with known Quaternary activity (motion within the last 1.6 m.y.) are depicted, along with a reference circle with a 100-km radius. Faults are color coded by recency of last motion, with historic activity (<150 years) shown in red, Latest Quaternary activity (<15,000 years) shown in orange, Late Quaternary activity (<130,000 years) shown in green, and undifferentiated Quaternary activity (<1.6 m.y.) shown in black.[2] Historic fault activity is recognized from direct observations of surface ground rupture and/or seismometer measurements of ground shaking. Older Quaternary fault activity is recognized from geologic fault investigations.

The most significant source of historical ground motion within 100 km of the AoI is the SAF. The SAF has been divided into 10 named sections, with the closest section to the AoI being the Cholame-Carrizo section. The Cholame-Carrizo section spans approximately 201 km of the 1,080-km total length of the SAF (Bryant and Lundberg 2002) and is well-known for its role in the formation of the Carrizo Plains geomorphic province. The most recent earthquake associated with the section was the magnitude 7.9 Fort Tejon earthquake of January 9, 1857 (SCEDC 2013b), which had an epicenter approximately 48 km west-northwest of the AoI. The recurrence interval for the San Andreas Cholame-Carrizo section is estimated at 160 to 450 years, and the fault creeps 33.9+/-2.9 mm/year (Sieh and Jahns 1984).

[2] The USGS/CGS Quaternary Fault and Fold Database (USGS and CGS 2020) does not include a separate category for Holocene activity (<11,700 years). Structures for human occupancy planned to be built within approximately 1/8-mile of a Holocene-active fault are subject to the Earthquake Fault Zone Investigation requirements of the Alquist-Priolo Earthquake Fault Zoning Act of 1972. The AoI is not located within an Earthquake Fault Zone. The closest Holocene-active fault to the Site is the SAF, approximately 21 km to the southwest.

Other significant Quaternary faults within 100 km of the AoI include the San Juan, Rinconada, and La Panza fault zones, located west of the SAF. Portions of the San Juan fault zone—at its northern extent near the SAF, approximately 50 km west-northwest of the AoI—have experienced activity in the Latest Quaternary, though the majority of the fault appears to be much less active (Bryant 2017). The Rinconada fault zone, approximately 71 km southwest of the AoI, has an estimated slip rate of 0.2 to 1 mm/year and an average recurrence interval of approximately 1,880 years (Wesnousky 1986). The La Panza fault zone appears to have had limited activity throughout the Quaternary (Bryant 2017).

North of the AoI is the Great Valley thrust fault system, which tips out at its southern end approximately 53 km north of the AoI. The Great Valley thrust fault system has a recurrence interval of 200 to 1,000 years and a slip rate of 1.0 to 5.0 mm/year (Namson and Davis 1988; Wentworth and Zoback 1990; Stein and Ekström 1992). Greater than 40 km east of the AoI are the Poso Creek, Pond, and Premier Faults (on the east side of the basin). These faults are unlikely to cause major ground motion within the AoI due to their distance from the AoI, size, and/or relative inactivity (Bryant 2017). South of the AoI are the Wheeler Ridge, Pleito, and White Wolf fault zones. The Wheeler Ridge fault zone is located approximately 77 km southeast of the AoI and experienced its most recent activity in the Latest Quaternary (Bryant 2017). The Pleito fault, located approximately 87 km southeast of the AoI, has a similar trend to the Wheeler Ridge fault zone, experienced Latest Quaternary activity, and is approximately 43 miles long (Bryant 2017). The Pleito fault has an estimated slip rate between 0.2 and 1.0 mm/year and an average recurrence interval of approximately 500 to 600 years (Hall 1984; Smith 1984; Jennings 1994). The White Wolf fault is located approximately 95 km southeast of the AoI (Bryant 2017). It has an average slip rate of 1.0 to 5.0 mm/year and experienced ground surface rupture during the Kern County Earthquake of 1952 (SCEDC 2013c).

Fault rupture probabilities based on the Uniform California Earthquake Rupture Forecast (Field et al. 2015) are shown for Quaternary faults located within 100 km of the AoI on **Figure 2.6-3**. Rupture probabilities shown represent the chance of occurrence of a magnitude 6.7 or greater earthquake over a 30-year period. Rupture probabilities are represented by a color gradient ranging from blue (0.01%) to pink (100%). The fault with the highest probability of producing a magnitude 6.7 or greater earthquake within 100 km of the AoI is the SAF. The portion of the Cholame-Carrizo segment of the SAF closest to the AoI has a mean 30-year probability of 21.45%. No other fault within 100 km of the AoI has a mean 30-year probability greater than 2% (Field et al. 2015).

As noted above, faults with known Quaternary activity and surface rupture have not been identified within the AoI. While there are active faults within the region that have the potential to produce significant shaking, none are expected to induce subsurface ruptures within the AoI. To evaluate seismic activity within the AoI, historical earthquake epicenters were examined.

2.6.2 Historical Earthquake Epicenters

Historical earthquake epicenters within a 100-km radius of the AoI, from the USGS Comprehensive Earthquake Catalog (USGS 2022), are shown on **Figure 2.6-4**. Events included have a recorded magnitude of 2.0 or greater and a date of occurrence between 1900 and 2022. Individual events are represented by white circles with radii proportional to their magnitude. The areas of highest

earthquake frequency occur along the SAF to the northwest of the AoI, the Great Valley Thrust Fault system to the north of the AoI, and the Wheeler Ridge, Pleito, and White Wolf faults to the southeast of the AoI. Over the same period, far fewer earthquakes occurred in the immediate vicinity of the AoI or on the Cholame-Carrizo segment of the SAF closest to the AoI.

Historical earthquake epicenters within a 15-km radius of the geographic center of the AoI are shown on four figures: **Figures 2.6-5** through **2.6-8**. Also shown on each figure is the 15 km-radius circle, the center point of the circle, and the limits of the AoI and the AoR. The data in these figures are drawn from two datasets: the USGS Comprehensive Earthquake Catalog (USGS 2023) and SCEDC Southern California Seismic Network Catalog (SCEDC 2023). Queries to both data sets included events of magnitude 2.0 or greater with a date of occurrence between 1950 and 2023. The minimum magnitude was selected to exclude events commonly characterized as "microearthquakes." The query start date of 1950 was selected because prior to this date, the minimum magnitude of events accurately resolvable by the available seismometer network was relatively high. Nonetheless, there is a relative paucity of events from the 1950s and 1960s in both data sets that may be attributed to sample bias. Continued seismometer deployment since the 1970s has allowed the accurate recording of smaller magnitude (<3.0) events.

Historical earthquake epicenters within a 15-km radius of the AoI from the USGS catalog are shown on **Figures 2.6-5** and **2.6-6**. On **Figure 2.6-5** earthquake epicenters are represented by gray circles with a radius proportionate to the associated event magnitude and color coded by depth of occurrence. On **Figure 2.6-6**, the same data are represented by placemarks, color coded by date of occurrence (decade). A total of 43 events of magnitude 2.0 or greater were recorded within the past 73 years. Over 88% of the events were below magnitude 3.0. Ten events were recorded within the AoI, each in the southern quadrant or along the southeast perimeter of the AoI. Of these ten events, only two occurred within the AoR. The magnitudes of the ten events recorded within the AoI ranged from 2.1 to 2.6.

Historical earthquake epicenters within a 15-km radius of the AoI from the SCEDC catalog are shown on **Figures 2.6-7** and **2.6-8**, following the data presentation style of **Figures 2.6-5** and **2.6-6**. Data from the SCEDC catalog are nearly identical to the USGS catalog. A total of 43 events of magnitude 2.0 or greater were recorded within the past 73 years. Over 85% of the events were below magnitude 3.0. Ten events were recorded within the AoI, each in the southern quadrant or along the southeast perimeter of the AoI. Of these ten events, only two occurred within the AoR. The magnitudes of the ten events recorded within the AoI ranged from 2.1 to 2.6. An earthquake magnitude of 2.6 corresponds to an area of fault slip with a diameter of approximately 700 meters (m), approximately 2,300 ft, or a radius of 350 m, approximately 1,150 ft (Zoback and Gorelick 2012).

Due to its regional proximity to the SAF, the CGS earthquake shaking potential map places the AoI within a moderate earthquake risk area; however, based on the record of earthquake events from the past 73 years, the AoI appears to be in a relatively low seismicity area of the western San Joaquin Basin. Since 1950, publicly available catalogs from the USGS and SCEDC consist of essentially identical events (in location and magnitude) totaling 43 recorded earthquakes within 15 km of the AoI. Of the total, albeit limited, events within 15 km of the AoI, only one exceeded

magnitude 4.0, approximately 11 km east of the AoR. Of the 10 events recorded within the AoI boundary, eight had hypocentral depths of 9 to 20 km bgs (29,529 to 65,620 ft bgs), one had a hypocentral depth of 4 to 9 km bgs (13,124 to 29,529 ft bgs), and one occurred at a poorly constrained shallow depth of less than 4 km bgs (<13,124 ft bgs). Of these 10 events recorded within the AoI, only two occurred within the AoR at depths between 9 and 20 km (29,529 to 65,620 ft). Due to uncertainty in the estimated depths of the recorded earthquake events, it is not possible to correlate the location of these events to specific faults of the North Belridge anticline. However, given that the average depth of the base of the 64 Zone W Sandstone is approximately 9,100 ft bgs within the geologic model domain, it appears that only the poorly constrained shallow earthquake could have been associated with fault slip at depths equivalent to or shallower than the injection zone. Tabulated historical seismicity data presented on **Figures 2.6-4** through **2.6-8** are provided in **Appendix 2E**.

Based on these observations, it appears unlikely that shaking resulting from an earthquake on the SAF or another known fault would induce slip on the pre-Quaternary inactive faults within the AoR that could result in a release of CO_2 from the storage complex. Earthquakes that may occur within the AoR during the operational lifetime of the CarbonFrontier CCS Project are likely to be below magnitude 3.0. Events of magnitude 3.0 produce fault displacements of approximately 1 millimeter to a few centimeters (Zoback and Gorelick 2012). Given that the average thickness of the Lower Santos Shale primary confining unit is approximately 260 ft within the AoR, and that the Santos Shale Member in its entirety has a maximum stratigraphic thickness of approximately 2,000 to 2,300 ft (see **Section 2.4**), the risk of earthquakes within the AoR producing sufficient offset to impact the CO_2 containment capacity of the storage complex is considered to be negligible.

2.7 Hydrologic and Hydrogeologic Information [40 CFR 146.82(a)(3)(vi), 146.82(a)(5)]

The climate of the southwestern San Joaquin Valley is semi-arid to arid, characterized by hot, dry summers and cool, moist winters. The average annual precipitation is 5 to 8 inches, which occurs primarily from November through April (Faunt 2009; DWR 2016). The average annual evapotranspiration rates for the region are approximately 53 to 55 inches per year (Faunt 2009). These low precipitation and high evapotranspiration rates in the AoI and vicinity explain the absence of perennial streams and little to no recharge to groundwater. There are no mapped springs within the AoI.

The southwestern San Joaquin Basin regional groundwater flow direction is generally to the east towards the San Joaquin Valley (Burton et al. 2012; Kern County Planning and Natural Resources Department 2020a). Within the AoI, however, the local hydraulic gradient is typically affected by local geologic structures, such as the anticlines and synclines that typify the western San Joaquin fold belt (Harding 1976; Aera 2014; Kern County Planning and Natural Resources Department 2020b).

The EPA, under the Safe Drinking Water Act, requires protection of USDWs that have TDS concentrations less than 10,000 mg/L. If the TDS concentration is greater than 10,000 mg/L, the formation can be considered a non-USDW. Oil-bearing formations include a mixture of typically

poor-quality to saline groundwater and hydrocarbons (Kern County Planning and Natural Resources Department 2020a). Within the North Belridge oil field, groundwater within the Tulare Fm and deeper formations is typically intermingled with oil.

The UIC program administered by EPA granted the California Department of Conservation Division of Oil, Gas and Geothermal Resources (DOGGR)[3] primacy to administer the UIC program in 1982. The oil- and gas-producing formations identified in the 1973 and 1974 California Oil and Gas Fields Volumes I, II, and III submitted in accordance with Section 1425 (a) of the Safe Drinking Water Act dated April 20, 1981, were exempt as USDWs (**Figure 2.7-1**; EPA 1982). In the North Belridge oil field, this includes the Tulare Fm, Etchegoin Fm, Monterey Fm, Temblor Fm, and Tumey Fm; whereas in the South Belridge oil field, this includes the Tulare Fm, Etchegoin Fm, and Monterey Fm.

In accordance with the EPA groundwater exemption criteria specified in Title 40, CFR, Part 146.4, on November 7, 2018, Aera and Greka submitted an Underground Injection Control Aquifer Exemption Application for the Tulare Formation, North Belridge oil field (Revision 1 [Aera and Greka 2018]) to the DOGGR and the SWRCB to expand the existing USDW-exempt areas of the North Belridge oil field. On July 26, 2016, Aera, Belridge Energy Resources, California Resources Corporation, E&B Natural Resource Management, Freeport-McMoran Oil & Gas, Linn Operating Inc., Vaquero Energy Inc., and West American Energy submitted an Underground Injection Control Aquifer Exemption Application for the Tulare Formation, South Belridge oil field (Aera et al. 2016) to expand the existing USDW-exempt areas of the South Belridge oil field. These documents were intended to demonstrate the groundwater within the Tulare Fm met the following EPA exemption criteria specified in Title 40, CFR, Part 146.4 (directly cited):

- It does not currently serve as a source of drinking water; and
- It cannot now and will not in the future serve as a source of drinking water because:
    - It is mineral-, hydrocarbon-, or geothermal-energy producing, or can be demonstrated by a permit applicant as part of a permit application for a Class II or Class III operation to contain minerals or hydrocarbons that considering their quantity and location are expected to be commercially producible, or
    - The TDS content of the groundwater is more than 3,000 mg/L and less than 10,000 mg/L and is not reasonably expected to supply a public water system or to have any other beneficial uses.

The applications were approved by EPA June 7, 2019 (EPA 2019) and March 13, 2020 [EPA 2020), respectively.

2.7.1 Groundwater Occurrence within Alluvium

Alluvium occurs throughout the AoI, except along and to the west of the North Belridge oil field anticline axis where the underlying Tulare Fm crops out (**Figure 2.7-2**). Within the AoR, the Alluvium is present along the eastern margin and in its southern portion. The Alluvium primarily

[3] Agency replaced by the California Energy Management Division (CalGEM) in 2020.

consists of interdigitated beds of sand, silt, clay, and gravel. The base of the Alluvium is marked by an unconformity that defines the contact with the underlying Tulare Fm within the AoI. The Alluvium extends from the ground surface to maximum depths of 425 ft TVD within the AoI and to approximately 385 ft TVD within the AoR. An isopach map of the Alluvium was constructed by subtraction of the seismically mapped and well-verified upper boundary of the Tulare Fm from a digital elevation model of the ground surface; because the upper bound of the Alluvium is the ground surface, this map also represents the depth to the base of the Alluvium (**Figure 2.7-3**). A list of wells used to define the base of the Alluvium/top of the Tulare Fm, as well as the base of the Tulare Fm, is provided in **Appendix 2F**. The Alluvium thickens away from the North Belridge oil field anticline axis towards the valleys/synclines to approximately 250 ft thick in the eastern portion of the AoI, with a maximum thickness of approximately 425 ft in the southern portion of the AoI.

Within the eastern and southern-most portion of the AoI, including the northern portion of the South Belridge oil field, groundwater within the Alluvium occurs as a perched zone atop the unconformity at the base of the Alluvium and/or upper clay layer within the Tulare Fm. In this area, alluvial groundwater consists of produced water from former produced water percolation ponds (see **Figure 2.7-1** for former disposal pond locations; Aera 2017; Aera and Greka 2018; EPA 2019; Wood Environmental & Infrastructure Solutions Inc. [Wood] 2021). This produced groundwater transitions into native groundwater to the east and northeast, with a mixed zone occurring between these two groundwater types (Aera 2017; Wood 2021, 2022). Native alluvial groundwater occurs to the east of the North Belridge oil field and within/to the east of the South Belridge oil field, where the western extent of native alluvial groundwater is controlled by the North and South Belridge oil field anticline structures (**Figure 2.7-4**; Wood 2019, 2021, 2022). There is no native alluvial groundwater within the southern portion of the North Belridge oil field (**Figure 2.7-5**; Aera 2014, 2017; SWRCB 2014; Wood 2022). Within the AoR, alluvial groundwater occurs in the southern-most portion only.

Publicly available groundwater elevation data and groundwater quality data from monitoring wells within portions of the Alluvium were compiled from the North and South Belridge oil fields and are presented in **Table 2.7-1** (Breitburn Operating LP [Breitburn] 2018a; Wood 2021, 2022; Groundwater and Environmental Services Inc. [GES] 2022). Of these 19 wells, only three wells[4] are located within the AoR. The potentiometric surface map for the Alluvium (**Figure 2.7-5**) indicates groundwater flow in the North Belridge oil field area to the north-northeast, and in the South Belridge oil field area to the east-northeast. There are no groundwater elevation data for the Alluvium in the northern half of the AoI, likely because the Alluvium is less than 150 ft thick (**Figure 2.7-3**) and the depth to groundwater, where available, is mostly greater than 150 ft (**Table 2.7-1**). Therefore, the Alluvium in the northern portion of the AoI is most likely dry due to the structural elevation.

Measured and calculated TDS concentrations for alluvial groundwater vary from 2,900 mg/L to 39,000 mg/L (**Figure 2.7-6**; Breitburn 2018a, 2018b; SWRCB 2018; Wood 2021, 2022; GES 2022). Where TDS concentrations exceed 10,000 mg/L, groundwater in the Alluvium can be

[4] Wells GWMP-5, MW-12G1, and 276(2)-26

considered a non-USDW. In contrast, areas where alluvial groundwater TDS concentrations are less than 10,000 mg/L are considered a potential USDW; however, such areas of the Alluvium lie outside of the AoR.

2.7.2 Groundwater Occurrence within Tulare Fm

The Tulare Fm outcrops across much of the North Belridge oil field and the western portion of the AoI (**Figure 2.7-2**). The Tulare Fm consists of interbedded oxidized to reduced sands and gypsiferous clay deposits and unconformably overlies the shallow marine San Joaquin/Etchegoin Fm (DWR 2003; Aera et al. 2016; Aera and Greka 2018). Within the Tulare Fm, there are multiple low-permeability clay layers which provide vertical seals that isolate groundwater within the Alluvium from the underlying Tulare Fm (Wood 2022) and have historically confined injected steam volumes to the oil-bearing portions of the Tulare Fm (Aera and Greka 2018). The Tulare Fm extends from the ground surface where it crops out to maximum depths of approximately 1,700 ft TVD in the southeastern portion of the AoI (**Figure 2.7-7**). Within the AoR, the Tulare Fm extends to a maximum depth of 1,130 ft TVD in the southeast. An isopach map of the Tulare Fm was constructed by subtraction of the seismically mapped base of the Tulare Fm from the top of the Tulare Fm merged with a DEM (**Figure 2.7-8**). The Tulare Fm thickens away from the crest of the anticlines in both the North and South Belridge oil fields, with a maximum thickness of approximately 845 ft in the southeastern portion of the AoR and approximately 1,450 ft in the eastern portion of the AoI.

The Tulare Fm is unsaturated (air sands) along the crest of the North and South Belridge oil field anticlines, within the AoR, and the air sand deposits thin towards the east of the AoI (Aera et al. 2016; Aera and Greka 2018). The first encountered fluids can be oil, or groundwater intermingled with oil, depending on location along the North and South Belridge oil field anticline structures and within the AoR. East of the North and South Belridge oil fields, and outside of the AoR, native groundwater occurs within the upper Tulare Fm (Wood 2022). Tulare Fm groundwater has TDS concentrations ranging from 6,055 to 22,540 mg/L within the North Belridge oil field (Area and Greka 2018). Within the South Belridge oil field, the Tulare Fm groundwater has TDS concentrations ranging from 4,300 mg/L to 33,985 mg/L (Aera et al. 2016). In the North and South Belridge oil fields, the Tulare groundwater boron concentrations have been reported to be between 6 and >100 parts per million, which is above the SWRCB drinking water Notification Level of 1 mg/L (i.e., 1 part per million) for boron (Aera et al. 2016; Aera and Greka 2018). The Tulare Fm is a non-USDW within the North and South Belridge aquifer exemption areas, and there is no groundwater quality data for outside of these areas within the AoI. Publicly available groundwater elevation data within the AoI are limited to a single depth to groundwater measurement, collected in 2006 from a well at 278 ft bgs (Wood 2019 and references therein). Without data to support otherwise, the Tulare Fm outside of the aquifer exempt areas within the AoI cannot be eliminated from consideration as a potential USDW.

In order to better constrain whether the Tulare Fm is a potential USDW outside of the aquifer exempt areas but within the AoR, Aera will develop a work plan for the collection of additional groundwater samples in the Tulare Formation outside the aquifer exemption area but within the

AoR. Results from the proposed sample collection efforts will be submitted to EPA under separate cover.

2.7.3 Potential USDWs

The Alluvium and Tulare Fm are considered to be potential USDWs over a portion of the area within the AoI outside of the aquifer exemption boundary (for the Tulare Fm), and/or where groundwater with TDS concentrations less than 10,000 mg/L is present (for the Alluvium and outside of the Tulare Fm exempt area). The injection zone is separated from these potential USDWs by numerous confining layers at depth including the Lower Santos Shale, the Upper Santos Shale, the Carneros Shale, and the Media Shale of the Temblor Fm; the McDonald Shale, Antelope Shale, and Reef Ridge Shale (or Belridge Diatomite) of the Monterey Fm; the Etchegoin Fm; and, locally, the San Joaquin Fm (**Figure 2.1-9**). The potential USDWs within the Tulare Fm are further isolated from the injection zone by the multiple confining clay layers within the Tulare Fm. These clay layers, as well as the basal unconformity of the Alluvium, further isolate the potential USDW within the Alluvium. The injection zone is on average 7,250 ft TVD below the Tulare Fm across the North Belridge oil field anticline, whereas the Alluvium, where present, is separated from the injection zone by a vertical distance of approximately 8,000 ft. The potential impacts of CO_2 injection on groundwater quality in the potential USDWs are expected to be minimal due to the following:

- The limited aerial extent of the potential USDWs within the AoI
- The elevated TDS concentrations (especially within the Tulare Fm)
- The confining units at the base of the Alluvium, within the Tulare Fm, and at depth
- The structural geometry of the North Belridge oil field anticline and injection zone
- The vertical distance separating the potential USDWs from the injection zone

2.7.4 Groundwater Occurrence within Deeper Formations

Within the North and South Belridge oil fields and the AoI, there are numerous non-USDWs. Deeper formations within the AoI, described below, are of a marine origin, are oil-bearing, and contain saline connate water (DOGGR 1998; Aera 2014). Therefore, groundwater in these formations within the AoI is not suitable for consumption. Furthermore, it has been reported that the estimated base of freshwater in the general area of the AoI is between 656 ft and 1,640 ft (Kang et al. 2020), which is shallower than the top of these formations.

The Etchegoin Fm contains shallow marine deposits, primarily composed of interbedded sandstones and mudstones, and is present along the flanks of the North Belridge oil field anticline and South Belridge oil field. According to DOGGR records, aqueous phase TDS concentrations for the Etchegoin Fm are greater than 10,000 mg/L (DOGGR 1998; Area and Greka 2018; Aera et al. 2016). Formation water from the Etchegoin Fm within the South Belridge oil field has reported TDS concentrations ranging from 19,000 mg/L to 26,000 mg/L and, therefore, this formation is not a USDW (DOGGR 1998; Area and Greka 2018; Aera et al. 2016).

The oil- and gas-producing zones of the Monterey Fm—including the Reef Ridge Shale (or Belridge Diatomite) Member, Antelope Shale Member, McDonald Shale Member, and Temblor Sands—have aqueous phase TDS concentrations greater than 10,000 mg/L (DOGGR 1998; Aera and Greka 2018; Aera et al. 2016). Furthermore, produced water from the Reef Ridge Shale Member has reported TDS concentrations ranging from 26,000 mg/L to 44,000 mg/L in the North Belridge oil field, and from 20,000 mg/L to 28,000 mg/L in the South Belridge oil field (Aera and Greka 2018; Aera et al. 2016). Based on these results, the Monterey Fm is not a USDW (DOGGR 1998; Area and Greka 2018; Aera et al. 2016).

The Temblor Fm contains several oil- and gas-producing zones (e.g., Carneros Sandstone, Agua Sandstone, and the 64 Zone Sandstones, which includes the U and W Sandstones) within the North Belridge oil field. Water samples from the 64 Zone Sandstones have TDS concentrations ranging from 21,000 mg/L to 41,000 mg/L (see **Section 2.8**). Aqueous phase TDS concentrations in the Carneros and Agua Sandstones are also greater than 10,000 mg/L and, therefore, these sandstones are not a USDW (DOGGR 1998). To better understand TDS concentrations and possible vertical variability in TDS, formation water samples will be collected from the Agua Sandstone and the Carneros Sandstone (first and second permeable units above the primary confining zone) for the purpose of geochemical characterization. These samples will be collected from monitoring wells upon their completion, as these wells will be screened in the target formations and are anticipated to provide representative samples from the monitored permeable formations.

2.7.5 Water Supply Wells within the AoI

Water supply well databases were reviewed for information on water wells within the AoI and adjacent area (1.5-mile buffer zone). This includes the California Geologic Energy Management Division (CalGEM), USGS, DWR, GeoTracker Groundwater Ambient Monitoring and Assessment (GAMA), Sustainable Groundwater Management Act, and the Kern County Environmental Health Well Permit online databases. The Kern County Public Health Services Department Environmental Health Division, West Kern Water District, Belridge Water Storage District, and Berrenda Mesa Water District were also contacted to identify whether there were additional water supply wells within the AoI and adjacent area and to evaluate the veracity of the wells on record.

Water wells identified by the above water districts, as well as the Kern County Public Health Services Environmental Health Department, were compared to wells identified from the CalGEM, USGS, DWR, GAMA, and the Sustainable Groundwater Management Act online databases to confirm that water wells were listed only once. When available, well completion reports were reviewed to evaluate the well usage and screened interval; however, the quality of these reports varied with many wells not having complete and/or legible publicly available documents. Additional well completion reports were requested from the Kern County Water Agency for water wells where online reports were not available. Where precise location information was not available, well locations were placed at the centroid of the section; however, field surveys have not been completed to verify well locations, use, status, or the existence of additional wells not included as part of the online databases. Wells identified through these public sources were compared to the internal database of the Water Resources Management group at Aera to confirm

their use and status and remove mislocated, destroyed, or misclassified wells. Several wells have been removed from further assessment based on operator knowledge.

Water supply wells identified within the AoI include one domestic well and one other/unknown/not specified well (**Figure 2.7-9**; **Appendix 2F**). There are no water supply wells within the AoR. Potential water supply wells within a 1.5-mile buffer zone around the AoI include one public well, three agricultural wells, and four other/unknown/not specified wells. Cathodic protection wells and monitoring wells were not included as part of this assessment. It is generally understood that other/unknown/not specified wells from public databases are typically groundwater monitoring wells. As a conservative approach, where documentation to support this could not be located, the other/unknown/not specified wells were retained in the well list.

Information on screened intervals was available for the domestic well within the AoI. The domestic well was screened from 125-300 ft bgs[5] within the Alluvium and the Tulare Fm. Output information from searched databases, including location information, use, and screened interval and/or well depth information (where available), along with available well completion reports, is provided in **Appendix 2F**.

The nearest potential water supply well is 0.95 miles east of the storage complex (**Figure 2.7-10**). The nearest municipal water supply wells are located approximately 11 miles east of the surface projection of the storage complex (**Figure 2.7-10**; Aera and Greka 2018). As part of the aquifer exemption process, the Dudley Ridge, Lost Hills, and Belridge Water Storage District were contacted by DOGGR, and it was confirmed that neither district nor individual growers have operational agricultural source wells within 1 mile of the North Belridge aquifer exemption boundary (Aera and Greka 2018).

2.7.6 Potential Impact of CO_2 Injection on Potential USDWs

The injection of CO_2 associated with the development of the proposed storage complex is not expected to impact the groundwater quality of potential USDWs. There are no known water supply wells or springs within the AoR (**Figure 2.7-9**), no USDWs have been conclusively identified within the AoR, and the areas where potential USDWs may be present (**Figure 2.7-11**) are limited to a total area of approximately 0.88 square miles along the western and eastern margins of the AoR.

There are no known USDWs in the Alluvium within the AoR, which is only present on the eastern/northeastern and southern margins of the AoR. In the eastern and northeastern portions of AoR the Alluvium is likely dry and, therefore, presumably cannot contain USDWs. Groundwater does occur within the Alluvium in the southeastern corner of the AoR, though it does not meet the criteria to be considered a USDW as TDS concentrations from monitoring wells[6] in the area exceed 10,000 mg/L.

[5] The depth of the screened interval for water supply wells is reported using nomenclature provided on the well completion reports, where ft bgs is equivalent to MD for groundwater wells.
[6] Monitoring wells within the AoR include GWMP-5 and MW-12G1 (**Figures 2.7-5** and **2.7-6**).

Throughout the portions of the AoR where Alluvium is absent, the Tulare Fm is exposed at the surface. Potential USDWs may be present in select areas of the Tulare Fm along the western margins of the AoR but have not been conclusively identified. The majority of the AoR is contained within the aquifer exemption areas for the Tulare Fm (**Figures 2.7-2** and **2.7-11)**. The AoR boundary extends slightly past the aquifer exempt areas to the east and west, but groundwater conditions in these areas are unknown. These areas on the eastern and western margins of the AoR are therefore considered to be potential USDWs. The potential for CO_2 injection to impact groundwater quality in the potential USDWs within the AoR is expected to be minimal, as there are approximately 7,250 vertical ft of strata (including numerous confining layers) separating the injection zone from the potential USDWs. Analysis of the potential impact of CO_2 injection on USDWs is discussed in greater depth in **Section 3** and **Attachment B**.

2.8 Geochemistry [40 CFR 146.82(a)(6)]

2.8.1 Geochemical Characterization Summary

Chemical data collected from solid, aqueous, and gaseous phases comprising the target CO_2 storage complex were evaluated to characterize geochemistry of the injection and confining zones and to inform the geochemical compatibility modeling of injectate gas with the target injection zone. The target injection zone, the 64 Zone Sandstones, consists of arkosic sandstone containing quartz overgrowth cements, detrital clay minerals (approximately 2–3% on average), and smaller amounts of clay (approximately 2% on average) and carbonate (approximately 1% on average) cements. The formation water of the 64 Zone Sandstones is slightly basic, brackish water that can be classified as having a sodium-chloride hydrogeochemical signature. The injectate gas is expected to be comprised primarily of CO_2 with minor amounts of impurities (approximately 1.3% of total composition).

Thermodynamic geochemical modeling was completed using the PHREEQC software package (Parkhurst and Appelo 2013), and thermodynamic/kinetic geochemical modeling was completed using the Geochemists Workbench™ (GWB) software package (Bethke 1998) to predict expected changes in mineral stabilities and identify geochemical reactions that may occur within the target injection zone as a result of interactions with the injectate gas.

Sensitivity analyses were performed to evaluate the potential impact of variable model inputs and injection zone ambient conditions on mineral stabilities. Variables evaluated via sensitivity analyses include ion activity model selection and pressure-temperature conditions.

Modeling results indicate that up to 14 different geochemical reactions may occur within the target injection zone following the introduction of injectate gas. These reactions are driven primarily by the dissolution of CO_2 into formation water and the subsequent decrease in pH and increase in alkalinity resulting from the dissociation of carbonic acid into aqueous bicarbonate and carbonate. These chemical processes drive changes in the thermodynamic stability of minerals comprising the 64 Zone Sandstones. Modeling results suggested that the precipitation of additional quartz overgrowth cement and carbonate cement and the dissolution of aluminosilicate minerals such as feldspars and clays may occur. Results suggested that these opposing reactions nearly balance total mineral mass changes, resulting in limited associated changes in total porosity of the 64 Zone

Sandstones. Kinetic modeling set to run over a 50-year period predicted a total porosity increase of approximately 0.15% (i.e., 0.15 porosity units) for the base model conditions and <2.0% (i.e., <2.0 porosity units) for pressure-temperature sensitivity conditions. Such an increase falls within the range of target injection zone total porosity measurements obtained from multiple methods, suggesting that overall injectivity is not expected to be substantially altered from geochemical reactions brought on because of gas injection. As such, target injection zone mineralogy and formation waters are considered to be compatible with the proposed gas injection.

2.8.2 Baseline Geochemical Characterization

2.8.2.1 Petrology/Mineralogy of the Injection Zone and Confining Unit

Geological characterization of the Temblor Fm is discussed in detail in **Section 2.1**. Mineralogy and petrology of the target injection zone and confining zone pertaining to geochemical compatibility modeling efforts are discussed primarily in **Section 2.4.2**, with an expanded discussion provided in this section as relating to geochemical compatibility modeling efforts.

Rock core samples from wells 17-2N, 4-1N, and 43-27N were analyzed for mineral identification (**Figure 2.2-5**). Locations of sample cores are shown in **Figure 2.4-11**. The sampled target injection zone wells are within the defined AoR model boundary. Well 17-2N is located near the center of the subsurface anticlinal structure with regards to lateral position and depth of the target injection zone (**Figure 2.2-5**). Wells 43-27N and 4-1N are located along the edge of the North Belridge oil field, and the target injection zone within these wells is within a down-dip portion of the anticline. As detailed in **Section 2.4.2.1**, collection of additional samples for mineralogical analyses (point-counting, XRD) from the U and W Sandstones will be attempted during the drilling of new wells in order to improve characterization of potential lateral and vertical heterogeneity within the target injection zone and to provide refined input for geochemical modeling.

The mineral identification results are provided in **Table 2.8-1**. Mineralogy results presented for wells 17-2N, 4-1N, and 43-27N were obtained via point-counting petrographic thin sections of the W Sandstone, using a standard light petrographic microscope with 300 points per thin section. Mineralogy results presented in the lower portion of **Table 2.8-1** for well 43-27N were obtained using XRD. One sample from the U Sandstone and two samples from the W Sandstone were analyzed via XRD from well 43-27N. Analytical reports associated with these datasets are included in **Appendix 2G** (petrographic point counting for samples from well 17-2N) and **Appendix 2D** (XRD). Despite differences between the two datasets, general trends within the injection zone XRD and point-count data appear to be similar.[7] Both datasets appear to indicate primary grain mineral abundances within similar ranges and comparable abundances of clay minerals. As indicated by XRD data, variation within 64 Zone Sandstones appears to be dominated by quartz-feldspar abundance differences, although XRD analysis does not have the capability to quantify lithic (rock) fragments which constitute the third type of primary grain. Point-count data from the three wells are considered to be representative of the injection zone mineralogy as the data are more

[7] Point-count and XRD data cannot be directly compared, as point-count data yields observed mineral abundances in percentages and includes pore space and lithic fragments, whereas XRD data yields individual mineral abundances in weight percentages.

comprehensive than the XRD results and do not contain variable ranges of abundances. Only one XRD sample is available for the U Sandstone. As indicated above, point-count and XRD data cannot be directly compared. When compared to XRD data from the two W Sandstone samples, the U sandstone sample contains more quartz (50-65 wt.% compared to 35-50 wt.%), slightly less feldspar (35-45 wt.% compared to 40-55 wt.%), identical carbonate (0 wt.% for the XRD samples), and slightly less clay-sized material (1-4 wt.% compared to 4.5-12 wt.%). The similarities observed between the U Sandstone and the W Sandstone XRD samples suggest that the U Sandstone is compositionally similar to the W Sandstone and that the more robust point-count dataset for the W Sandstone adequately represents the holistic composition of the 64 Zone Sandstones.

The point-count dataset contains mineralogical samples collected over a depth range of 8,482 to 9,119 ft from three wells within the W Sandstone (**Table 2.8-1**). Four trends in mineralogy as a function of increasing depth are identifiable from data at location 17-2N:

- A general slight decrease in quartz abundance with increasing depth is observed across the entire sampled interval.
- A general slight increase in plagioclase feldspar abundance with increasing depth is observed across the entire sampled interval.
- An increase in the total clay-sized fraction abundance within the basal portion of the W Sandstone is observed with increasing depth, beginning at approximately 8,822 ft and continuing to the base of the sampled interval (this trend was noted in **Section 2.4.2.1**., with the noted interval containing an average abundance of 8.5% clay, compared to an average abundance of 3.7% clay in the overlying interval of the W Sandstone).
- A decrease in abundance/absence of kaolinite within the basal portion of the W Sandstone is observed beginning at approximately 8,829 ft in depth and continuing through the base of the sampled interval (this interval contains an average of 0.3% kaolinite, compared to an average kaolinite abundance of 2.3% in the overlying interval).

The vertical heterogeneity in mineralogy noted above will be further characterized as part of the additional proposed sampling and may be considered in future modeling efforts, if necessary.

Sandstone petrology is typically classified based on the ratio of common detrital components: quartz, feldspar, and lithic (rock) fragments, referred to as a Q:F:R ratio. This ratio forms the basis of sandstone petrologic interpretation by indicating the relative proportion of common clastic components. The 64 Zone Sandstones are classified as arkosic sandstone with an average thin section point-count measurement Q:F:R ratio of 60:32:8 (**Table 2.8-1**, normalized to exclude other minerals). Point-count data from three cores (17-2N, 4-1N, and 43-27N) spanning the 64 Zone Sandstones were presented in Kaczorowski et al. (1986) and are shown on a ternary diagram (**Figure 2.4-12**). The samples presented in **Figure 2.4-12** plot within arkosic sandstone classification, indicating petrologic conformity within the target injection zone.

Detailed discussion of the Santos Shale mineralogy is provided in **Section 2.4.2**. The Santos Shale Member of the Temblor Fm consists of the Upper Santos Shale and the Lower Santos Shale which

are separated by the Agua Sandstone (**Figure 2.1-9**). The Lower Santos Shale directly overlies the target injection zone and is, therefore, considered the primary confining unit. The average composition of the Santos Shale (undifferentiated) is classified as an argillaceous/siliceous mudstone based on the classification scheme of Gamero-Diaz et al. (2012). This classification is supported by the academic dataset encompassing the entire Santos Shale and the XRD results of samples collected from the Upper Santos Shale for the purposes of this evaluation.

The Santos Shale contains high total organic carbon content, which ranges from 1.4 to 15.8 wt.% with an average of 7.7 wt.%. The high total organic carbon content is attributed to the oxic ocean depositional environment (Mitchell 2018; Mitchell and Guo 2018). As detailed in **Section 2.4.2.2**, collection of additional samples for mineralogical analyses (point-counting, XRD) from the Lower Santos Shale will be attempted during the drilling of new wells to improve characterization of potential lateral and vertical heterogeneity within the primary confining unit.

Geochemical modeling of interactions between formation water in the primary confining unit, injectate gas, and the confining unit mineralogy was not completed due to the perceived lack of reactivity expected between pore fluids and the fine-grained shale comprising the confining unit. Lower porosity/permeability associated with shale lithologies compared to the 64 Zone Sandstones significantly restricts the surface area of the formation in contact with injectate gases and formation water, thus increasing the activation energy required to initiate mineral reactions. Quartz and feldspar minerals within mudstones are expected to be geochemically inert. The clay mineral component may be subject to alteration reactions between clay minerals. Illitization of smectite within shales at comparable temperature and depth systems is common, although this process is controlled by pressure and temperature conditions more so than geochemical changes and would likely not be influenced by injection of CO_2-dominated gas. Such reactions may result in dehydration as interlayer water particles exit the solid-phase, but significant changes in porosity and permeability are not expected to occur as a byproduct (Colton-Bradley 1987). Carbonate minerals are likely to be the only component vulnerable to geochemical changes initiated by injectate gas. As evidenced in petrographic analyses of the Upper Santos Shale, carbonate minerals were typically observed as sand-sized fossil fragments within ductily deformed detrital clay matrix. As such, very little injectate gas would be expected to interact with these carbonate grains due to the low permeability of the bulk rock caused by the detrital clays. The potential impact of these reactions is significantly mitigated by the mudstone's low permeability and the limited surface area in contact with fluids along the injection zone-confining unit interface. Therefore, the Santos Shale is believed to be compatible with the proposed CO_2-dominated injection gas stream.

2.8.2.2 Characteristics of the Injection Zone Formation Water

Formation water samples were collected from the following wells on the following dates:

- 43-27N on October 22, 1985
- 17-2N on November 20, 2003
- 25-26N on September 4, 2014
- 25-26N on January 16, 2017

- 3-22N on December 21, 2021

Data for one additional sample collected from a well (ID: BN5) screened within the 64 Zone Sandstones is available in McMahon et al. (2018). Data from these five primary well samples and the 64 Zone well from McMahon et al. (2018) were incorporated into the geochemical models.

The wells listed above contain perforated intervals (corresponding to the water sample depth) spanning at least part of the 64 Zone U Sandstone and part of the 64 Zone W Sandstone. The locations of wells with reported formation water analytical results are shown in **Figure 2.4-11**. Formation water samples were analyzed for various parameters depending on the purpose of sample collection. Parameters considered for geochemical modeling include major cations (calcium, magnesium, sodium, and potassium) and anions (chloride, sulfate, and alkalinity [CO3 + HCO3]), pH, sulfide, iron, manganese, boron, barium, aluminum, silica, and strontium. Laboratory analytical reports for these samples are provided as **Appendix 2G.** Results of laboratory analyses are summarized in **Table 2.8-2**.

64 Zone Sandstone formation water samples display consistent geochemical facies regardless of the well location and sampling depth, indicating geochemical conformity of 64 Zone Sandstone formation waters. Major ion chemistry of these waters is dominated by sodium and chloride, as displayed on a Piper Diagram on **Figure 2.8-1**. These waters contain a calculated average TDS concentration of 30,848 mg/L, which is defined by USGS as brackish and is close to average seawater salinity levels (approximately 35,000 mg/L). The six samples considered in the geochemical modeling inputs fall within a calculated TDS range of 21,060 to 41,000 mg/L. Formation water pH levels are neutral to slightly basic, with an average pH value of 7.1 standard units. High TDS/salinity concentrations result in an average specific gravity value of 1.02 g/cm^3 and an average electrical conductivity value of 43.95 millimhos per centimeter.

While specifics regarding groundwater sample type and collection (e.g., sampling methodology, sample preservation) are not available, laboratory reports do not indicate the presence of data qualifiers or data quality issues (**Appendix 2G**). Although issues associated with sample preservation/holding times/laboratory QA/QC were not identified on laboratory analytical reports; should these issues exist, they have the capability to impact the quality of ionic composition data and generate uncertainty in subsequent geochemical modeling inputs, which may propagate as iterative geochemical calculations are completed. Steps taken to combat the potential impact of such issues include assessment of data quality for each sample using charge-balance calculations (**Table 2.8-2**), and usage of one representative formation water sample for geochemical modeling by averaging values from each available sample to mitigate the potential impact of erroneous results from individual samples.

Calculation of formation water TDS/salinity was also attempted using resistivity and porosity logs (Rwa method) because the 64 Zone W Sandstone is a relatively clean sandstone (low clay content). However, at the 43-27N well location (one of the locations with reported water analysis), residual hydrocarbon saturation appears to result in underestimation of formation water salinity, as compared to direct laboratory analysis. Off-site (outside the AoI) well Gump Trust 30-1, which was logged with an advanced logging suite in a borehole without significant washouts over the 64

Zone W Sandstone interval, displays a clear oil-water contact around 11,575 ft MD (**Figure 2.4-28**). Pickett plot methodology (equivalent to the Rwa method) using log resistivity and porosity data from uncemented portions of the wet sand (water leg) interval (**Figure 2.8-2**) shows that the formation water resistivity at Gump Trust 30-1 is approximately 0.1 ohmmeters. At a reservoir temperature of approximately 250 °F, that resistivity value results in a formation water salinity range between 17,000 and 20,000 mg/L (expressed as NaCl), which is close to the direct measurement TDS value obtained from water analysis in well 43-27N.

Additional formation water samples will be collected to improve geochemical characterization and refine geochemical model inputs. The additional water samples will be collected from monitoring wells screened in the injection zone (U and W Sandstones) and in the permeable formations overlying the confining zone (Agua and Carneros Sandstones) during pre-operational well testing. In addition to the analyses presented in this section, the samples will be analyzed for dissolved metals (including aluminum) using EPA Method 6010B, as well as for bicarbonate and carbonate concentrations. Aera will attempt to collect a sufficient number of samples at specific targeted depths to identify potential aqueous geochemical stratification which may exist within the target injection zone. Aera intends to collect formation fluid samples from the injection zone in new and repurposed injection wells by using a bottom-hole sampler or by swabbing. Where possible, downhole sampling will be used to characterize vertical variability in fluid properties by acquiring samples from approximately five representative depths within the U and W Sandstones at each newly drilled injection well. The sampling depths will be determined using wireline logs to ensure proper vertical coverage while sampling from sufficiently permeable intervals. In addition, sampling of formation water from the monitoring wells following gas injection will be attempted to evaluate the degree of aqueous geochemical change associated with interaction of the system with injectate gas.

2.8.2.3 Injectate Composition

The expected composition of the gas stream for injection will be comprised of a combination of three product streams: Aera's pre-combustion and post-combustion CO_2 streams plus future third-party sources (**Section 7.0**). The average injectate composition is expected to consist of approximately 50% Aera sources, further divided into 17% pre-combustion and 83% post-combustion products, and 50% from third-party sources. Chemical compositions of the products, as well as the combined composition calculated based on expected product fractions, are provided in **Table 2.8-3**. Carbon dioxide is expected to account for 98.7% of the injectate mass. The remaining 1.3% of the injectate mass will consist of a mixture of impurities which are not expected to significantly interact with injection zone minerals at present concentrations (e.g., argon gas has not been documented to impact clastic mineral stabilities). The only notable difference between Aera's pre- and post-combustion CO_2 streams and third-party sources is the possible presence of small amounts of hydrogen (H_2) gas (<1% by volume). This minor amount of H_2, if present in the final CO_2 stream, is not expected to have material implications to geochemical interactions with reservoir minerals and fluids based on academic modeling and observational studies (Kampman et al. 2016; Shi et al. 2020; Heinemann et al. 2021).

2.8.3 Geochemical Modeling Setup

Geochemical modeling was conducted using two approaches: thermodynamic considerations only, and thermodynamic + kinetic considerations, with the purpose of evaluating the reactivity of the system comprised of formation solids, formation water, and injectate gas in the proposed injection zone. Geochemical modeling goals included the following:

- Evaluate mineral-water equilibrium conditions in the system before and after gas stream injection to identify mineral stability changes.
- Identify geochemical reactions thermodynamically favored to occur following gas injection.
- Estimate the potential impact of these geochemical changes on the physical properties of the target injection unit (with regards to total mineral mass and porosity).

Geochemical modeling was conducted using the USGS software package PHREEQC (Parkhurst and Appelo 2013) for the thermodynamic assessment, and GWB (Bethke 1998) for the combined thermodynamic and kinetic assessment.

2.8.3.1 Model Input

As discussed in **Section 2.8.2.1** above, the point-count mineralogy dataset consisting of wells 17-2N, 4 1N, and 43-27N characterizes the target injection zone mineralogy. Mineralogical inputs for geochemical modeling were generated by calculating the mean observed abundances from thin section point-counting analyses, normalized to 100% to remove the contributions of pore space and unspecified lithic fragments. Previous studies have indicated that clay mineralogy is predominantly composed of kaolinite, with some illite and mixed-layer I/S which has been predominantly illitized (transformed to illite) (Taylor and Soule 1993). To estimate the percent contribution of these clays in the model input, the mean kaolinite mineral abundance calculated from point-counting analyses was subtracted from the mean mineral abundance of the entire clay-sized fraction. The remaining clay abundance was assumed to be 85% illite and 15% smectite, following conclusions from Taylor and Soule (1993). The presence of anhydrite was noted in previous studies, but it was not detected in the point-counting analyses; as such, anhydrite was included in the solid phase mineralogy at 0.05%. Normalized mineral abundances were then converted to units of moles per liter using a total bulk density of 2.64 kilograms per liter based on laboratory grain density testing (**Appendix 2G**). The calculated model inputs for solid phase mineralogy are provided in **Table 2.8-4**. Solid phase model input conditions may be updated following acquisition of additional mineralogical data. Subsequent modeling runs will be updated accordingly.

Six formation water samples were collected or documented in academic studies within the target injection unit on different dates and from distinct locations, as described in **Section 2.8.2.2**. The chemical compositions of these samples were averaged to generate a representative formation water composition for the model input. This representative composition contained a calculated charge imbalance error of -7.37%. Variations due to sampling methods and analytical uncertainty associated with standard laboratory methods may result in minor variations in calculated charge balance values. Charge imbalance error within +/- 10% is typically considered to be an acceptable balance, although +/-5% is ideal for brine solutions. While the representative formation water

sample used in modeling exceeds this 5% idealized threshold, no QA/QC issues were reported on laboratory reports.

While compositional variability within individual samples would be expected to alter model results, an aggregate composition approach was selected to define formation water geochemistry due to the general geochemical similarity of the six samples that define the aqueous geochemical model input. The Piper diagram provided as **Figure 2-8.1** demonstrates the ubiquitous classification of the collected formation water samples as sodium-chloride dominant water types. Although absolute concentrations of key constituents do vary between samples, the relative proportion of major ions remains very similar. The concentration variability between samples is reflected in TDS values. TDS concentrations for formation water samples range from 21,060 mg/L to 41,000 mg/L, as discussed in **Section 2.8.2.2** above. While this range is notable, the formation water samples can be classified as brackish water. The general geochemical consistency of formation water samples as sodium-chloride dominant brackish water is the basis for the aggregate composition approach.

Geochemical modeling involving aluminosilicate minerals (feldspars and clays) requires an aqueous aluminum concentration as a model input. None of the formation water samples defining the aqueous model input were analyzed for aluminum. To arrive at a plausible aluminum concentration for the representative formation water composition, an equilibrium model run was generated in PHREEQC with aluminosilicate minerals manually set to equilibrate with the aqueous input solution at the formation pressure and temperature conditions used in the subsequent base case model run. The modeled aluminum component in solution was estimated to be 0.02 mg/L, which is reasonable for a sandstone aquifer at approximately neutral pH (Oehman 1988). This value for aqueous aluminum concentration was then added to the model input. The complete aqueous model inputs defining formation water considered representative in this evaluation based on available data are provided in **Table 2.8-5**. Representative formation water geochemical conditions may be updated following acquisition of additional injection zone formation water samples as discussed in **Section 2.8.2.** Subsequent modeling runs will be updated accordingly.

Model runs were set up using the previously described input for formation water and target injection zone mineralogy. A representative porosity value of 13% (based on the mean log-derived porosity of the U and W Sandstones [**Table 2.4-4**]) was used to define injection zone pore space (effective porosity). For the base case scenario, temperature was set to 112.8 °C (235 °F), as presented in California Oil & Gas Fields, Volume 1 – Central California (CD-1) by DOGGR (1998) for the reservoir temperature of the 64 Zone Sandstones in the North Belridge oil field. For the base case scenario, pressure was set to 47.63 atmospheric units (atm) (700 pounds psi), based on understanding of the current reservoir pressures within the target injection zone (see **Figure 2.3-8**). The number of moles in one liter of gas at 47.63 atm and 112.8 °C, according to the ideal gas law, was calculated to be 1.504 moles. Based on the expected injectate composition including Aera's pre- and post-combustion product and third-party sources (98.7% CO_2 when combined), the model input included 1.484 moles of CO_2, or a CO_2 fugacity of 47.01 atm. This fugacity was supplied as a model input, and CO_2 solubility within formation water was estimated in both

modeling software programs based on temperature, pressure, and compositional inputs using a Henry's Law approach (Bethke 1998; Gundogan et al. 2011; Parkhurst and Appelo 2013).

Following methods proposed in Tremosa et al. (2014) for modeling geochemical compatibility of geologic carbon sequestration, geochemical modeling efforts employed a batch reactor modeling approach where the geochemical system comprised of mineralogy, formation water, and injectate gas is assumed to be a perfectly mixed reactor with homogenous distribution of every chemical compound and reactant.

The target injection zone consists of a multiphase porous system in which pore space is saturated with formation water, oil, and/or gas. Compositional data for oil and gas within the formation are not available and therefore were not incorporated into the geochemical modeling efforts. As a result, geochemical modeling focused on investigating the impact of injectate gas on the mineral-water system which directly influences mineral stability calculations.

Geochemical modeling software packages use databases of laboratory-generated thermodynamic data to calculate mineral solubility relative to aqueous solutions. The Lawrence-Livermore National Laboratory database (LLNL.dat) contains the most robust assemblage of thermodynamic information for the mineral system comprising the target injection unit and was therefore used for this evaluation. This database includes thermodynamic data appropriate for the pressures and temperatures applicable to the target injection zone. However, TDS concentrations in the 64 Zone Sandstone formation waters are categorized as brackish to highly saline. As such, the Pitzer database (pitzer.dat), which utilizes the Pitzer equations as the ion activity model in the calculations (Pitzer 1973), may be a more appropriate database to model waters of high salinity. The Pitzer ion activity model was used in a series of sensitivity analyses to assess the impact of ion activity model selection on geochemical modeling results. A discussion of the implementation and results of the thermodynamic database sensitivity analysis is provided in **Appendix 2G.** Ion activity model sensitivity testing was completed only within the PHREEQC models, as the expanded Pitzer database used in the sensitivity model runs was formatted specifically for PHREEQC and is not compatible with other geochemical modeling software platforms. Comparison of sensitivity results from the LLNL database and the expanded Pitzer database indicates that differences for most parameters are relatively minor, suggesting a limited influence of ion activity model selection. Sensitivity modeling predicted that the geochemical reactions expected to occur would proceed in the same direction regardless of database selection. The primary differences observed between ion activity model selections was associated with the initial saturation states of a small number of relevant minerals. Further discussion is provided in **Appendix 2G**. These observations support the conclusion that both databases provide reasonable predictions of mineral reactivity.

2.8.3.2 Equilibrium Modeling

Geochemical equilibrium calculations were completed to evaluate possible changes in mineral masses and aqueous parameter concentrations resulting from three-phase (injection zone mineralogy, formation water, injectate gas) system equilibrium. Equilibrium modeling was completed by inputting mineral concentrations calculated from analytical data into the model

(**Table 2.8-4**) and manually fixing individual mineral saturation indices (SIs) to a value of zero in the presence of the formation water and injectate gas. A mineral SI is a measure of mineral-water thermodynamic equilibrium specific to a particular mineral. It is calculated using the equation:

$$SI = log_{10}(\frac{IAP}{K_{sp}})$$

where Ksp is the mineral solubility product, which is defined in the thermodynamic database, and IAP is the ion activity product, which is the product of the activity of individual components of a mineral reaction. The activity of an aqueous species is a calculated value which expresses how a particular concentration of that species behaves in a solution of a particular ionic strength. Aqueous activities are conventionally considered to be equivalent to concentration values in dilute to near-dilute solutions. Activities deviate from aqueous concentrations as ionic strength increases.

If a mineral SI is greater than zero, precipitation of the mineral out of solution is thermodynamically favored. If a mineral SI is less than zero, dissolution of the existing mineral into solution is thermodynamically favored. If a mineral SI is approximately zero, then the mineral is in thermodynamic equilibrium with the solution and no precipitation/dissolution reactions are expected to occur. A mineral is functionally considered to be in thermodynamic equilibrium with pore fluid if the mineral SI is within +/- 0.2 of zero. Manually fixing the SI of a mineral to a value of zero forces chemical equilibrium within the model by forcing aqueous activity changes within the formation water, allowing changes in mineral mass and aqueous concentrations resulting from liquid-mineral-gas interactions (e.g., mineral precipitation/dissolution) to be quantified.

2.8.3.3 Reaction Pathway Modeling

Reaction pathway modeling was completed by inputting known system components into the model and calculating the responses of mineralogy and aqueous geochemistry to the presence of the injectate gas. Reaction pathway geochemical modeling was completed using both PHREEQC (thermodynamic considerations only) and GWB (thermodynamic and kinetic considerations). A key difference between equilibrium modeling and reaction pathway modeling is that the SIs of minerals comprising the target injection zone are not manually set to equilibrate; rather, mineral abundances and aqueous concentrations are provided as model inputs and the system's interactions with the injectate gas are calculated either as a function of mineral kinetics over a set time interval (applicable to the GWB approach) or until the system has completely equilibrated independent of kinetic considerations (applicable to the PHREEQC approach). GWB model runs were initially set to calculate interactions over a 50-year time interval to evaluate the impact of mineral kinetic precipitation/dissolution rates on physical properties of the 64 Zone Sandstones following gas injection. It is likely that some mineral reactions will not proceed to completion over the defined 50-year interval. In such instances the equilibrium modeling results provide an assessment of changes after reactions have proceeded to equilibrium. A 50-year time interval was selected for kinetic modeling to provide reasonable predictions in mineral mass and aqueous concentration changes through the immediate future based on mineral-specific reactivity rates and surface areas.

As with equilibrium modeling, reaction pathway modeling assumes a batch reactor approach. Model inputs were entered into PHREEQC and SIs representing the present state of mineral-water

interactions prior to gas injection were calculated. These SIs define the current thermodynamic state of minerals within the target injection zone. The model was then rerun and SIs were recalculated after introducing the injectate gas at the fugacity indicated in the above sections. Mineral SIs before and after the addition of the injectate gas were then compared to evaluate the impact of the injectate on the stability of individual minerals.

Modeling was also completed using the React module of GWB to incorporate mineral kinetic considerations into compatibility calculations. Mineral reaction rate constants from Palandri and Kharaka (2004) and mineral surface area values from Beckingham et al. (2017) were applied to the model to assess reaction progress based on thermodynamics and precipitation/dissolution kinetics. Mineralogy, aqueous geochemistry, and injectate composition were provided as inputs, and the model was set to calculate resulting reactions over a 50-year time interval. Fifty years was selected for the kinetic modeling to assess mineral reactions which are expected to proceed relatively quickly (on a scale of years as opposed to a geologic time scale). Slower reactions will not proceed to completion during the defined time interval and are instead addressed via equilibrium modeling without the inclusion of kinetic considerations. Selecting the 50-year time interval was also deemed adequate in part based on current understanding of the time scale of reaction rates for commonly anticipated carbon sequestration mineral reactions in sandstone reservoirs (Tremosa et al. 2014; Tutolo et al. 2015). Outputs from the GWB model display changes in geochemical components over the defined time interval.

2.8.4 Geochemical Modeling Results and Discussion

2.8.4.1 Equilibrium Modeling

Predicted aqueous concentration changes from equilibrium modeling in PHREEQC are provided in **Table 2.8-6**. These results can be interpreted as the difference (Δ) between the average composition of formation water from laboratory testing (the initial input) and the final composition following forced equilibration of formation minerals and injectate gas. Predicted changes in aqueous concentrations would occur as a result of gas dissolution into formation waters and adjustment of mineral stabilities in response to the subsequent geochemical changes. Predicted solid-phase changes from equilibrium modeling in PHREEQC are shown in **Table 2.8-7**. Like aqueous components, these results can be interpreted as predicted changes in mineral mass in response to injectate gas interaction.

Table 2.8-6 indicates a predicted decrease in pH resulting from dissolution of CO_2 into formation waters. The most significant predicted changes in aqueous concentrations following gas injection were observed for sodium, alkalinity, calcium, iron, potassium, and sulfate. Alkalinity would be expected to significantly increase as CO_2 dissolves into formation water, causing the formation of carbonic acid which would in turn dissociate into bicarbonate while simultaneously lowering pH. A significant increase in sodium concentrations was predicted, likely a result of destabilization and partial dissolution of plagioclase framework grains triggered by pH changes. Notable increases in aqueous iron, potassium, and sulfate concentrations were observed in model results, although not to the same degree as for alkalinity and sodium. Predicted increases in iron and potassium are likely associated with dissolution of clay minerals. Decreases in calcium and magnesium concentrations were predicted. These decreases are likely associated with the formation of

secondary minerals such as re-precipitated carbonates (i.e., dolomite). Aqueous silica concentrations were also predicted to decrease.

Table 2.8-7 indicates minor increases in predicted mineral abundances for quartz, kaolinite, and dolomite, decreases in predicted mineral abundances for calcite, plagioclase, illite, smectite, and anhydrite, and relatively little change in the other minerals present in the target injection zone. Predicted solid-phase changes corresponded with predicted aqueous-phase changes:

- The increase in quartz mass corresponds with the decrease in aqueous silica concentration.
- The increase in kaolinite mass corresponds with the decrease in plagioclase mass, as kaolinite is known to form at the expense of feldspars.
- The decrease in plagioclase mass corresponds with the increase in aqueous sodium concentration.
- The increase in dolomite mass corresponds with the decrease in aqueous magnesium concentrations.
- The decrease in illite and smectite mass may correspond with the increase in aqueous potassium and iron concentrations.

2.8.4.2 Reaction Pathway Modeling

Saturation index results calculated in PHREEQC for individual minerals in the target injection zone before and after interaction with injectate gas are provided in **Table 2.8-8**. Of the existing minerals in the target injection zone, K-feldspar, albite (plagioclase), dolomite, calcite, illite, kaolinite, smectite, and glauconite SIs were predicted to decrease relative to present conditions following the introduction of injectate gas. SIs for quartz and anhydrite remained nearly unaltered following injectate gas interaction. These results are generally in agreement with the predicted mineral mass changes indicated in **Table 2.8-7** for equilibrium modeling, except for kaolinite, which was predicted to increase in mass based on equilibrium modeling despite a slight decrease in SI based on reaction pathway modeling, and dolomite, which was predicted to slightly increase in mass based on equilibrium modeling despite a decrease in SI based on reaction pathway modeling.

Each model run contained additional minerals which were thermodynamically favored to precipitate following gas injection (contained a positive SI). The LLNL calculations primarily indicated the thermodynamic stability of iron-oxyhydroxide minerals, although these minerals contained greater positive SIs prior to injectate interaction, indicating that their stability has been and should continue to be thermodynamically favorable, and their absence from reported mineralogical analyses may be due to very low abundances or kinetic barriers to their formation. The expanded Pitzer database calculations indicated thermodynamic favorability of multiple calcium-aluminosilicate minerals along with iron-oxyhydroxide minerals, although these minerals were also thermodynamically stable prior to injectate gas interaction.

Predicted changes in aqueous concentrations of major ions resulting from the kinetic React model (within the GWB software package) are shown on **Figure 2.8-3**. Kinetic reaction pathway

modeling indicated that aqueous concentrations of calcium, magnesium, and chloride would be expected to decrease following interaction with injectate gas, whereas concentrations of sodium, bicarbonate, and sulfate would be expected to increase. These results agree with the results of equilibrium modeling using PHREEQC, with the exception of chloride which was predicted to increase slightly based on equilibrium modeling. Predicted changes in pH of formation water are shown on **Figure 2.8-4**.

Predicted mass changes for individual injection zone minerals are shown on **Figure 2.8-5**. As with equilibrium modeling using PHREEQC, mineral mass changes were predicted to be minimal (+/- 0.4 mole for each mineral). React modeling using mineral kinetic values predicted dissolution of albite (plagioclase), anhydrite, dolomite, glauconite, illite, kaolinite, K-feldspar, and smectite. React modeling predicted minor increases in mineral mass of quartz and calcite. Calcite was predicted to dissolve initially as pH decreased due to CO_2 dissolution into formation waters but would be expected to reprecipitate as aqueous bicarbonate concentrations increased in formation water. Minor quartz precipitation was predicted (Δ mol of 0.02635 over the 50-year time interval). Total predicted mineral mass change is shown graphically on **Figure 2.8-6**. The kinetic reaction pathway model predicted <5 kilograms per cubic meter of total mineral mass loss. The impact of this predicted mass loss on porosity is shown on **Figure 2.8-7**. The kinetic reaction pathway model predicted a minor porosity increase of approximately 0.0015 (i.e., 0.15% or 0.15 porosity units) to the total porosity value of 0.13 (13% or 13 porosity units) over the 50-year time interval resulting from dissolution of framework grains and clay minerals. This porosity increase contrasts with the predictions from non-kinetic equilibrium modeling, which suggested (but did not quantify) a minor porosity decrease based on a predicted increase in total mineral mass (predominantly a result of quartz precipitation). The effect of this mass increase on porosity cannot be calculated based on inputs provided to the PHREEQC model.

2.8.4.3 General Discussion of Modeling Results

The primary mechanism driving geochemical change in the modeled system is the dissolution of CO_2¬ injectate gas into formation waters. At a pressure of 47.63 atm, a fixed number of 1.484 moles were added as model input representing CO_2. The CO_2 is predicted to dissolve into formation waters, resulting in the formation of carbonic acid based on the following reaction:

$$CO_2(g) + H_2O \rightleftharpoons H_2CO_3$$

which then dissociates into bicarbonate following the reaction below:

$$H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$

Further dissociation into carbonate may occur following the reaction below:

$$HCO_3^- \rightleftharpoons H^+ + CO_3^{2-}$$

These processes result in a pH decrease in formation waters, which would influence the stability of minerals comprising the injection unit. Carbonate (dolomite and calcite) cements present in the 64 Zone Sandstones are the most sensitive to pH changes and would be expected to function as buffers to pH decreases, initially dissolving into solution as pH drops. Reaction pathway model results of carbonate SI changes reflect this conclusion, as shown on **Table 2.8-8**. Model results

indicate that SIs for dolomite and calcite would change from positive values, indicative of favored precipitation, to negative values, indicative of dissolution resulting from CO_2 injection. Carbonate abundances in the 64 Zone Sandstones are minimal, based on XRD, point-counting, and HCl solubility data (mean of <1%), and thus, porosity changes resulting from dissolution of carbonates are expected to be minimal. Of note, kinetic reaction pathway modeling predicted a slight increase in calcite mass over a 50-year time interval, which is related to a predicted decrease in aqueous calcium concentrations. Calcite was predicted to initially dissolve in response to pH decreases, then reprecipitate out of formation water as alkalinity concentrations increase due to the above reactions. The reprecipitation process constitutes a mineral trapping mechanism, as reprecipitation of carbonate minerals would trap CO_2 chemical components in the solid phase.

The 64 Zone Sandstones are comprised primarily of quartz. Quartz is a geochemically inert mineral that typically does not undergo chemical reactions. Comparison of SIs for quartz before and after the introduction of injectate gas revealed very little change (**Table 2.8-8**). However, equilibrium modeling results indicated that precipitation of quartz cements (1.06 moles per liter [mol/L] based on the expanded Pitzer model and 2.62 mol/L based on the LLNL model) is thermodynamically favorable (**Table 2.8-7**). Kinetic reaction pathway modeling in React also indicated that precipitation of quartz cements should occur (**Figure 2.8-5**). Formation of quartz cements account for the net mineral mass increase predicted in PHREEQC modeling; in contrast, the React model calculated a net decrease in total mineral mass due to quartz cement formation being outpaced by dissolution of other minerals.

Dissolution of plagioclase feldspar is predicted by both model types as a result of pH decreases in this pressure-temperature regime. Equilibrium modeling indicated that K-feldspar should remain stable; however, both reaction pathway models suggested that dissolution of K-feldspar should occur. Dissolution of plagioclase feldspar would result in the contribution of calcium, sodium, aluminum, and silica to formation water. Geochemical modeling efforts assumed an albite (sodium plagioclase endmember) composition for plagioclase, which accounts for the predicted increase in aqueous sodium concentrations following plagioclase dissolution. The presence of anorthite (calcium plagioclase endmember) would result in an increase in aqueous calcium concentrations relative to modeling results presented herein. Dissolution of K-feldspar would result in an increase of aqueous potassium concentrations to formation waters, which was observed in model results (**Table 2.8-6**).

The aqueous components of dissolved plagioclase may precipitate out of solution as the clay mineral kaolinite. Equilibrium modeling results predicted the dissolution of plagioclase feldspars and the subsequent precipitation of kaolinite at the expense of feldspar dissolution (**Table 2.8-7**). SI comparisons from reaction pathway modeling support the dissolution of plagioclase (**Table 2.8-8**), although SIs for kaolinite decrease slightly. Likewise, the kinetic React model also predicted a slight decrease in total kaolinite mass (**Figure 2.8-5**). Dissolution of plagioclase grains would constitute an increase of primary porosity within the target injection zone, but the potential precipitation of kaolinite, should it occur, would offset much of the total mineral mass and associated porosity changes (Δ = +0.826 mol/L kaolinite compared to Δ = -1.25 mol/L

plagioclase). If kaolinite precipitation does not occur, dissolution of feldspar grains would result in minor mineral mass decreases and an increase in porosity.

Formation water was found to be highly supersaturated with respect to glauconite prior to gas injection (SI of 22.68). Reaction pathway modeling results using PHREEQC indicated that the introduction of injectate reduced the SI of glauconite to -3.18, which is indicative of undersaturation. The React model also predicted dissolution of glauconite over a 50-year time interval. Equilibrium modeling predicted no change in glauconite mass. Glauconite does not occur in large abundances within the 64 Zone Sandstone (0.1% [**Table 2.8-1**]), so potential porosity created by dissolution of glauconite is expected to be minimal.

Modeling results indicated that a change in anhydrite stability is not anticipated. Equilibrium modeling predicted no change in anhydrite mass, and reaction pathway modeling indicated that SI changes are minor following interaction with injectate gas. React modeling predicted a minor decrease in anhydrite mass, although such a change would be negligible in relation to total formation solids mass changes, as anhydrite was not observed in petrographic analyses.

Overall, changes to mineral mass and subsequent changes to porosity are predicted to be minimal following the system interaction with injectate gas. PHREEQC modeling incorporating only thermodynamics, and GWB React modeling incorporating thermodynamics and kinetics, predicted different overall porosity trends. Both models predicted quartz precipitation, which would reduce porosity. The discrepancy between these trends is a result of the amount of predicted dissolution of other minerals and the amount of predicted precipitation of quartz. Equilibrium modeling using PHREEQC predicted that quartz precipitation should slightly outpace the dissolution of other minerals, whereas kinetic reaction pathway modeling predicted that other mineral dissolution should outpace quartz precipitation. Despite the slight discrepancy in total mineral mass changes, both model types predict similar solid and aqueous phase geochemical changes brought on by similar mechanisms.

Geochemical modeling results suggest that up to 14 reactions may occur as a result of gas injection. These reactions are as follows:

- CO_2 dissolution into formation water
- Carbonic acid dissociation into bicarbonate
- Bicarbonate dissociation into carbonate
- Dissolution of K-feldspar
- Dissolution of plagioclase feldspar
- Dissolution of illite
- Dissolution of smectite
- Potential dissolution of kaolinite
- Initial dissolution of carbonate cements

- Precipitation of quartz cement
- Potential precipitation of kaolinite
- Reprecipitation of carbonate cements
- Potential precipitation/dissolution of Fe-oxyhydroxides[8]
- Potential precipitation of calcium aluminosilicate[9] minerals

An additional reaction, precipitation of dawsonite, was predicted to occur when the system was subjected to pressure-temperature conditions associated with sensitivity analyses presented in **Appendix 2G**. Full stoichiometry for each of the above listed chemical reactions is provided in **Appendix 2G**. Geochemical modeling efforts identified expected chemical reactions and evaluated the potential impact of these reactions on physical properties of the target injection area via total mineral mass and porosity changes. As part of a sensitivity analysis, additional model runs were performed using different temperature and pressure values because these conditions are expected to change as the injectate accumulation lowers the temperature and increases the pressure in the injection zone (**Appendix 2G**). Modeling using variable sensitivity conditions yielded a maximum absolute porosity increase of <0.02 of the 0.13 total porosity (i.e., an increase of <2% or <2 porosity units, relative to the total porosity of 13% or 13 porosity units) over a 50-year period, compared to a <0.002 (i.e., <0.2% or <0.2 porosity units) increase for the base case model conditions.

The 64 Zone Sandstones were not expected to undergo extensive petrologic modification following the introduction of injectate gas because much of their composition consists of geochemically inert quartz grains. This hypothesis was evaluated via geochemical modeling of mineral stability and aqueous composition changes resulting from interaction with injectate gas. Results indicate that largely offsetting minor mineralogical changes should occur, culminating in a predicted total porosity change of <0.2% under base case conditions over a 50-year time period. Modeling was also completed under variable pressure-temperature conditions to attempt to assess the maximum extent of physical change within the target injection zone under pressure-temperature regimes potentially achieved during the injection process. This sensitivity testing yielded a maximum total porosity increase of <2.0% over a 50-year time period (**Appendix 2G**). Considering that assessments of mean porosity within the target injection zone range from 9.9% to 13% depending upon methodology, the maximum predicted porosity change is not considered significant enough to warrant incorporation of geochemical reactions into the AoR modeling effort.

2.9 Other Information (Including Surface Air and/or Soil Gas Data, if Applicable)

As described in **Attachment E**, surface air and soil gas monitoring are not required for this Project. No additional relevant information under this subsection is being provided.

[8] Calculated SIs suggest that Fe-oxyhydroxides were thermodynamically more stable prior to injectate gas interaction, but still remain stable following gas interaction.
[9] Calculated SIs suggest that calcium aluminosilicate minerals were thermodynamically more stable prior to injectate gas interaction, but still remain stable following gas interaction.

2.10 Site Suitability [40 CFR 146.83]

The detailed geologic characterization provided in previous sections of this application demonstrates that the proposed storage complex meets the suitability requirements set forth at 40 CFR 146.83. This section provides further support for the proposed storage complex injectivity, confinement, and storage capacity with respect to the CO_2 injectate within the AoR.

2.10.1 Injectivity

The AoR has a long history of production, injection, and operating experience providing support of reservoir injectivity. A detailed discussion of the 64 Zone U and W Sandstones of the injection zone (the 64 Zone Sandstones) is provided in **Section 2.4**. Available well data presented below support reservoir injectivity:

- The discovery well 64-27N established production at 61,200 thousand standard cubic feet per day (MSCFD) in gas phase alone through 2.875-inch tubing and native reservoir pressures.
- In 1946, the field reported approximately 36,000 MSCFD (approximately 1,830 equivalent CO_2 metric tons/day) gas injection into 64-27N and 64-35N combined using 2.875-inch tubing, a surface pressure of approximately 1,375 psi gauge, and an estimated reservoir pressure of approximately 1,100 psi gauge.
- Wells 43-16N and 18-35N currently receive 8,600 barrels per day water injection (approximately 1,110 equivalent CO_2 metric tons/day using a wellhead density of 813 kilograms per cubic meter) with no surface pressure with 2.875-inch tubing.

More precise estimates of CO_2 injectivity are derived from a 1950 three-point gas injection test performed in 64-35N. A discretized wellbore PROSPER model was built to match the gas test results and calibrate the model to the reservoir and well conditions before running predictions and sensitivities for CO_2 injection modeling.

Calibration on the 64-35N test was achieved using K*h=3,000 milliDarcy feet (mD.ft) (permeability * height), which is in line with the geological permeability model and a skin=0. A more conservative, 1,000 mD.ft case was also generated. Assuming skin=0 is appropriate at this stage because there is some equivalency in the injectivity behavior between higher skin or lower 'K*h,' and skin can be enhanced by well stimulation techniques (**Section 5.1**). Though somewhat uncertain, 'K*h' is relatively well informed by the reservoir well control fed into the stratigraphic and permeability models and can be biased more favorably towards the higher range during the injection location selection.

Results of the well injectivity sensitivity evaluation are presented in **Figure 2.10-1**. The high case shows up to 5,000 metric tons/day injection capacity, and the more conservative scenario shows closer to 2,000 metric tons/day.

Figure 2.10-1 presents plots of 4.5-inch-tubing CO_2 injectivity versus reservoir pressure from the calibrated PROSPER model with predictions adjusted for fracture pressure limits. Note that the injection pressure constraints (80% of fracture pressure) are the reason why the injectivity profiles

have a plateau area at 5,000 and 2,000 metric tons/day in the early time of the high and low scenarios, respectively, instead of a strictly monotonically decreasing function against reservoir pressure.

The conclusions of this work are as follows:

1. Injectivity in the conservative scenario remains as high as 2,000 metric tons/day or about 40,000 MSCFD of CO_2.
2. Higher quality reservoir areas could accommodate a larger rate with little to no limitation by maintaining bottom-hole pressure below 80% of the fracture pressure.
3. In areas of the reservoir where the characteristics are not as favorable, the injection is manageable at safe rates by reducing the flow rate or the surface pressure while monitoring bottom-hole pressure.

Overall, 64 Zone injectivity is sufficient to support CO_2 injection given proper sizing of the tubing, manageable well skin, sufficient pressure differential with the reservoir, surface control, and pressure monitoring.

2.10.2 Confinement [40 CFR 146.83(a)(2)]

Descriptions of the AoR stratigraphy and structure in **Sections 2.1**, **2.3**, and **2.4** demonstrate that the proposed AoR is characterized by a porous and permeable injection zone overlain by a laterally continuous and impermeable confining zone, both of which are folded to form a broad anticline. These favorable reservoir properties and geometries, which trapped oil and natural gas over geological timescales, are expected to serve to trap buoyant CO_2 and constrain the plume's lateral extents.

The primary confining zone, the Lower Santos Shale, has an average TVT of approximately 275 ft within the AoR and a maximum thickness of approximately 400 ft on the west of the anticline in the northwestern portion of the AoR (**Figure 2.4-10**). The Santos Shale Member (comprised of the Lower Santos Shale, the Agua Sandstone, and the Upper Santos Shale) extends far beyond the AoR and is regionally reported to reach a maximum stratigraphic thickness of 2,000 to 2,300 ft (Adkinson 1973). Detailed discussions of the injection and confining zones and their individual facies, including the depth, areal extent, and thickness, as well as their porosity, permeability, mineralogy, and geochemical characteristics, are presented in **Section 2.4** and **Section 2.8**. Characterization of the Santos Shale Member, as presented in previous sections, demonstrates high suitability for use as the confining zone.

Published literature (Foss and Blaisdell 1968; Carter 1985), as well as the petrologic and petrophysical analyses presented in **Section 2.4**, indicate that the Upper and Lower Santos Shales are clay-rich mudstones with low permeability. Log and core analysis data presented in **Section 2.4.3** display a difference of at least two (and up to six) orders of magnitude in permeability between the 64 Zone Sandstones and the Upper and Lower Santos Shale, indicating that fluids will be confined to the 64 Zone Sandstones. Capillary pressure measurements also report markedly higher entry pressures for the Upper Santos Shale, as compared to the 64 Zone Sandstones,

suggesting that the confining zone can support a thick column of injected CO_2 without leaking. Mercury entry pressures range between 5.14 psia and 49.15 psia (0.039 and 0.339 megapascals) for samples from the 64 Zone Sandstones, while ranging between 2,498 psia and 6,649 psia (17.2 and 45.85 megapascals) for the five Upper Santos Shale samples (**Figure 2.4-26**).

Section 2.3.1 shows that the primary confining zone's fractures are very limited and without detrimental effect on the macroscopic sealing capacity of the zone, while the injection zone is effectively unfractured. Consequently, fractures are expected to have a negligible influence on the sealing capacity of the primary confining zone and the transmissivity of the injection zone.

The mechanical integrity of the primary confining zone was examined using the in-situ stresses calculated from the 3D geomechanical model and presented in **Table 2.5-2**. The stresses predicted in the Lower Santos Shale are calculated to be below the stress level that would indicate failure (1.00), assuming the formation has zero cohesive strength and with a friction angle of 31º (**Table 2.5-1**). A shear or tensile stress level of 1.00 would be required to move the Lower Santos Shale stress state into critically stressed condition from the current static state, as described in **Section 2.5**. The results of the confining zone integrity analysis suggest within the model constraints that the confining zone is stable without risk for shear or tensile failure.

For the faults identified in the AoR (**Section 2.3.2**), 90 years of detailed production records and pressure data (**Section 2.3.3**) indicate that these large-scale faults do not transmit fluids or pressure. The fault stability analyses presented in **Section 2.3.3.2** indicate that the existing non-transmissive faults will not become critically stressed and will not introduce up-fault fluid flow risks under the proposed injection and storage pressures (**Section 2.5**). Proposed injection pressures will be, by design, below the pressure required to initiate and propagate new fractures.

Finally, the geochemical characterization (**Section 2.8**), combined with the lack of driving force for the CO_2 stream to enter the confining zone, suggests the confining zone will not to be affected by the injectate.

The preceding paragraphs, in conjunction with robust well construction and corrective action plans (presented in **Section 5** and **Section 3**, respectively), lead to the conclusion that the AoR is capable of permanently sequestering CO_2.

As discussed in **Section 2.6**, it is unlikely that shaking resulting from an earthquake on the SAF or another known fault would induce slip on the pre-Quaternary inactive faults within the storage complex that could result in a release of CO_2 from the storage complex. Earthquakes that may occur within the storage complex during its operational lifetime are likely to be below magnitude 3.0. Events of magnitude 3.0 produce fault displacements of approximately 1 millimeter to a few centimeters (Zoback and Gorelick 2012). Given that the average thickness of the Lower Santos Shale primary confining unit is approximately 275 ft TVT, and that the Santos Shale Member in its entirety has a maximum stratigraphic thickness of approximately 2,000 to 2,300 feet (see **Section 2.4.1**), the risk of earthquakes within the AoR producing sufficient offset to impact the confinement of the CO_2 injection units is considered to be negligible.

2.10.3 Storage Capacity [40 CFR 146.83(a)(1)]

CO_2 storage capacity in the 64 Zone Sandstones was estimated using the Oil and Natural Gas Reservoirs Production Method, as described in the National Energy Technology Laboratory's Carbon Storage Atlas (United States Department of Energy 2015). This methodology converts surface volumes of produced oil and gas to subsurface CO_2 volumes, on a volume-for-volume basis as detailed in **Table 2.10-1.**

As shown on **Table 2.10-1**, the material balance using cumulative hydrocarbons (oil and gas) produced from the 64 Zone within the AoR resulted in a high estimate of 42.6 MM mt of potential CO_2 storage capacity.

A conservative estimate of storage capacity was generated using material balance of only free gas from the reservoir's gas cap, which constitutes the most accessible storage target. The total volume of original gas in-place is estimated at 545 billion cubic feet (BCF), made up of 333 BCF of free gas in the reservoir's gas cap and 212 BCF of dissolved gas. Records show that 514.5 BCF of the initial 545 BCF has been produced from the 64 Zone (see **Attachment B**). Using a highly conservative assumption (i.e., that 212 BCF of the dissolved gas was produced) would yield 302.5 BCF of gas produced from the free gas cap—more than 90% of the initial gas cap volume, with an estimated 95% of that coming from the 64 Zone within the AoR. A rapid decline in reservoir pressure during the early decades of 64 Zone production further substantiates that the gas cap was depleted and necessitates a high recovery factor. This conservative gas cap recovery factor of 90% yields a similarly conservative CO_2 storage capacity estimate of 22.9 MM mt of CO_2.

A mid-range estimate at 32.7 MM mt of CO2 storage capacity is proposed using an average of the low and high range estimates of 22.9 and 42.6 MM mt, respectively, as summarized in **Table 2.10-2**.

The geochemical analysis presented in **Section 2.8** predicts a low reactivity of the injection formation with the injectate leading to minimal porosity or permeability changes over time. Additional data presented in the well construction (**Section 5**) and the corrective action (**Section 3**) sections demonstrate the limited reactivity of the injectate with legacy or sequestration well materials.

The information presented herein demonstrates that the proposed CarbonFrontier location meets the minimum criteria for siting (40 CFR 146.83).

3. AOR AND CORRECTIVE ACTION

The CarbonFrontier Area of Review and Corrective Action plan pursuant to 40 CFR 146.82(a)(4), 146.82(a)(13), 146.84(b), and 146.84(c) describes the modeling approach and results to establish the AoR, tabulation and evaluation of wells for corrective action, and AoR reevaluation schedule and criteria. The Area of Review and Corrective Action Plan is included as **Attachment B**.

5. INJECTION WELL CONSTRUCTION

Aera plans to repurpose five existing wells and construct four new-drill wells for injecting CO_2 at North Belridge Field in the 64 Zone Sandstones. Five additional existing wells will be repurposed for monitoring the injection zone and the dissipation zone above the injection zone.

In compliance with 40 CFR 146.82(a)(11), 146.82(a)(12), and 146.86, **Attachment K** (Construction Details) and **Appendix 5A** contain well specific construction details, procedures, design criteria, current and planned wellbore schematics, and well surveys for the planned Class VI CO_2 injection and monitoring wells. Because well architectures vary, both **Attachment K** and **Appendix 5A** have separate sections for each existing well to be repurposed, as well as a section for the plan that applies to the four proposed new wells. **Table 5-1** provides a summary of the wells included in **Attachment K** and **Appendix 5A**. The four proposed new injection wells are listed in **Table 5-2. Figure 5-1** indicates the structural location for each repurposed and new well in the North Belridge oil field.

5.1 Proposed Stimulation Program [40 CFR 146.82(a)(9)]

Aera believes that the injection zone (64 Zone Sandstones) will require stimulation in the Project injection and monitoring wells, including wells either repurposed to or newly drilled for Class VI service. Details and methods proposed for stimulation are included in **Attachment J**.

5.2 Construction Procedures [40 CFR 146.82(a)(12)]

5.2.1 New Drill Wells for CO_2 Injection

Conductor casing will be set for drilling and taking circulation returns for the surface casing hole and cementing the surface casing.

The surface casing hole will be drilled through the base of potential USDWs to 1,000 ft (40 CFR 146.86[b][2]). Deviation check surveys will be taken while drilling at sufficiently frequent intervals to determine the location of the borehole and to document that vertical avenues for fluid movement in the form of diverging holes are not created (40 CFR 146.87[a][1]). The surface casing will be run and cemented to surface as required by 40 CFR 146.86(b)(2). While there are no USDWs present at the proposed well location, the surface casing will be set and cemented as if an USDW is present. The casing will be pressure tested prior to drilling out the shoe to confirm mechanical integrity.

The intermediate casing hole section will be drilled through the Temblor Sands to a depth of approximately 6,100 ft. Deviation check surveys will be taken while drilling (40 CFR 146.87[a][1]). The intermediate casing will be run and cemented to surface. A two-stage cement job is planned to provide cement to surface. The intermediate casing will isolate oil and gas zones while drilling the injection casing hole section to the base of the primary confining zone (the Lower Santos Shale). Cement to surface will provide an additional barrier to prevent the leakage of CO_2 from the injection zone to surface, into unauthorized zones, and into potential USDW. The casing will be pressure tested prior to drilling out the shoe to confirm mechanical integrity.

The injection casing hole section will be drilled to the top of the injection zone (the 64 Zone Sandstones), which is the same depth as the base of the primary confining layer (the Lower Santos

Shale). Deviation check surveys will be taken while drilling (40 CFR 146.87[a][1]). The injection casing will be run using a sufficient number of centralizers, to the top of the injection zone (the 64 Zone Sandstone) and cemented to surface (40 CFR 146.86[b][3]). More than one cement stage may be necessary (40 CFR 146.86[b][4]). The evaluation logs will confirm that the annulus cement will prevent the movement of fluids between zones and hence prevent movement of CO_2 to unauthorized zones in the well and potential USDW zones as required by 40 CFR 146.86(a)(1). The casing will be pressure tested prior to drilling out the shoe to confirm mechanical integrity.

The long string casing design will consist of materials compatible with exposure to the injected fluids (40 CFR 146.86[b][1]). The cement and additives will be compatible with the injection and formation fluids as required by 40 CFR 146.86(b)(5). Casing centralizers will be used to centralize the casing and liner to 70% standoff or greater as per 40 CFR 146.86(b)(3).

The injection liner hole section will be drilled through the injection zone. Deviation check surveys will be taken while drilling (40 CFR 146.87[a][1]). The injection liner will be run and cemented to the top of the liner. The evaluation logs will confirm the annulus cement will prevent the movement of fluids between zones and prevent movement of CO_2 to upper zones in the well. The liner will be pressure tested after it is cleaned out to confirm mechanical integrity.

The injection well will be completed by perforating the authorized injection zones. Completion equipment consisting of a packer, monitoring equipment, and tubing will be installed. The flow wetted components of the packer, tubing, and wellhead will also use material compatible with the injected fluid. Noncorrosive packer fluid treated with corrosion inhibitors and biocide will be circulated in the tubing-by-casing annulus as per 40 CFR 146.88(c).

Open and cased hole well logging details for both new and repurposed existing wells are included in **Attachment D**.

5.2.2 Repurposed Wells for CO_2 Injection

The completion equipment will be removed, and the well will be cleaned out to the required depth for injecting into the 64 Zone Sandstones injection zones. Casing inspection and annulus evaluation logs will be run to confirm that the annulus seal through the confining layer is sufficient to prevent movement of fluids behind the existing long string casing.

A new inner casing will be run and cemented to surface. The inner casing design will consist of materials compatible with exposure to the injected fluids (40 CFR 146.86[b][1]). The cement and additives will be compatible with the injection and formation fluids as required by 40 CFR 146.86(b)(5). A sufficient number of casing centralizers will be used to centralize the casing and liner to 70% standoff or greater as per 40 CFR 146.86(b)(3). The new long-string inner casing will isolate the existing casing, thereby resulting in a wellbore that meets Class VI requirements. The casing will be pressure tested prior to drilling out the shoe to confirm mechanical integrity.

Aera will install and cement new liners across the injection zone in the five repurposed injection wells. Each liner will be cemented to the top of the liner. The new inner liner and cement will be compatible with the injection stream as per 40 CFR 146.86(b)(5) and will isolate the existing liner

from the injected fluids. The liner will be pressure tested after it is cleaned out to confirm mechanical integrity.

The injection well will be completed by perforating the authorized injection zones. Aera will maintain at least a 20 ft separation between the base of the primary confining zone and the top wellbore opening to the injection zone below to reduce the potential for loss of containment (40 CFR 146.82[a][9]). Completion equipment consisting of a packer, monitoring equipment, and tubing will be installed. The flow wetted components of the packer, tubing, and wellhead will also use material compatible with the injected fluid (40 CFR 146.86[c][1]). As per 40 CFR 146.88(c), the tubing-casing annulus will be circulated and filled with non-corrosive packer fluid.

5.2.3 Repurposed Monitoring Wells

The construction procedures for repurposing the five existing wells to monitoring wells are similar to repurposing wells for injection. The differences include perforation intervals in the appropriate zones to be monitored, and smaller outer diameter tubing will be used as long as the tubing inner diameter is large enough to allow running wireline logging tools and downhole sampler equipment that are planned to meet periodic monitoring requirements as required by 40 CFR 146.86(a)(2).

Repurposed monitoring wells that require an inner liner will have a new inner liner run and cemented to the top of the liner. The new inner liner and cement will be compatible with both the injection stream and reservoir fluids as per 40 CFR 146.86(b)(5). Liners will be pressure tested after clean-out to confirm mechanical integrity.

5.2.4 Mechanical Integrity Assurance during Well Repurposing and Drilling

After each casing and liner are set and cemented, and after the tubing and packer are installed, they will be pressure tested to a pressure equal to or greater than the design pressure for that component to demonstrate mechanical integrity. The simulation design load input pressures for the injection well tubing and tubing by casing annulus are as follows:

- Maximum tubing injection pressure 2,800 psi
- Maximum annulus pressure 2,900 psi
- Maximum shut-in tubing pressure with methane 3,950 psi

The simulation design load input pressure loads on the monitor well tubing and tubing by casing annulus are as follows:

- Maximum shut-in tubing pressure with CO_2 1,850 psi
- Maximum shut-in tubing pressure with methane 3,950 psi

5.2.5 Cement Bond, Temperature, and Inspection Logs

After the long-string inner casing and inner liner have been cemented, a cement bond and variable density log and a temperature log will be run as required by 40 CFR 146.87(a)(3)(ii) to document an annular seal. A baseline wall thickness inspection log will also be run.

5.2.6 Downhole Monitoring Equipment

Injection and Monitoring wells will be equipped with downhole devices and equipment to measure and monitor downhole conditions. The wells will be designed to allow the use of testing and monitoring devices and workover tools as required by 40 CFR 146.86(a)(2). Downhole monitoring equipment includes (1) a downhole pressure internal tubing and/or tubing-casing annulus gauge and (2) distributed temperature sensors (DTS) and/or distributed acoustic sensors (DAS). The pressure line will be strapped to the outside of the tubing for data transmission to surface for data collection and monitoring. The DTS and/or DAS line will be in the cemented B-annulus between the inner (injection) casing and the outer casing. The annuli will be sized to allow for data lines and clamps to be installed for downhole monitoring devices lines.

The DTS and/or DAS will be used to conduct the annual external mechanical integrity test as required by CFR 146.90(e).

The inner diameter of the tubing planned for monitoring wells will be sized to allow running wireline logs such as pulsed neutron, saturation, pressure, and noise. In addition to logs, downhole samplers can be run through the tubing to recover fluid samples from the reservoir. The inner diameter of the tubing planned for injection wells is sized for the planned injection rate.

5.2.7 Alarm and Safety Shut-In System for Injection Wells

The well monitoring system will consist of sensors for measuring temperature, pressure, and flow. Data from the sensors will be collected and stored in a Supervisory Control and Data Acquisition (SCADA) system. Monitored parameters will have high and low alarms that will be activated when a measured parameter is outside its normal operating range. When a critical parameter, such as pressure, alarms, the well will be shut in by a fail-safe actuated gate valve that is a component of the injection tree. Operating personnel will be notified that an alarm was activated. The cause for the alarm will be investigated to determine what actions are necessary to demonstrate that the well is safe. If the well appears to be lacking mechanical integrity, the UIC Program Director will be notified within 24 hours (40 CFR 146.88[f][3]). After needed repairs or maintenance are conducted, and mechanical integrity has been demonstrated to the satisfaction of the UIC Program Director (40 CFR 146.88[f][4]), the well can then be returned to active injection.

A landing nipple profile will be installed near the packer to allow setting a plug or other downhole safety device if required for well maintenance and servicing. **Figure 5.2-1** shows a schematic of the safety system.

In addition to the surface monitoring equipment shown in **Figure 5.2-1**, a processing server may be on selected locations for continually monitoring subsurface injection and tubing-casing annulus pressures above the packer, temperature (DTS), and/or acoustic (DAS) data. The detailed designs, equipment specification, and selection will be completed and submitted to EPA prior to project startup.

5.2.8 Alarm and Safety Shut-in System for Monitoring Wells

The well monitoring system will consist of sensors for measuring temperature and pressure on the tubing and the tubing-casing annulus (40 CFR 146.88[e][1]). Data from the sensors will be collected and stored in a SCADA system. Monitored parameters will have high and low alarms

that will be activated when a measured parameter is outside its accepted normal operating range. When a critical parameter, such as pressure, alarms, the well will be shut in by a fail-safe actuated master valve that is a component of the tree (40 CFR 146.88[e][2]). Operating personnel will be notified that an alarm was activated. The cause for the alarm will be investigated to determine what actions are necessary to demonstrate that the well is safe. If the well appears to be lacking mechanical integrity, the UIC Program Director will be notified within 24 hours (40 CFR 146.88[f][3]). After needed repairs or maintenance are conducted, and mechanical integrity has been demonstrated to the satisfaction of the UIC Program Director (40 CFR 146.88[f][4]), the well can then be returned to service.

A landing nipple profile will be installed near the packer to allow setting a plug or other downhole safety device if required for well maintenance and servicing. **Figure 5.2-2** shows a general schematic of the safety system.

In addition to the surface monitoring equipment shown in **Figure 5.2-2**, a processing server may be on selected locations for continually monitoring subsurface injection and tubing-casing annulus pressures above the packer, temperature (DTS), and/or acoustic (DAS) data. The detailed designs, equipment specification, and selection will be completed and submitted to EPA prior to project startup.

5.2.9 Well Materials Compatibility

Well construction materials were selected that are compatible with the injection stream and reservoir fluids according to 40 CFR 146.86(b)(1) and 40 CFR 146.86(c)(1).

5.2.9.1 Material Selection for Casing, Liners, Tubing, and Packers

The material selected for the flow-wetted well construction components is modified 13Cr (13% Cr, 5% Ni, 2% Mo). The selection was based on modeling using the corrosion analysis program OLI[10] to evaluate the casing, liner, and tubing corrosion rates caused by exposure to the CO_2 injection stream (**Section 2.8.2.3**) and reservoir fluid (**Section 2.8.2.2**), in compliance with 40 CFR 146.86(b)(1)(ix); see the FEED study report included as **Appendix 5B** for additional details on the corrosion modeling and results used to select the modified 13Cr material. Modeling results (**Appendix 5B**) confirmed an acceptable corrosion rate for modified 13Cr material for the life of the Project to meet the well materials compatibility requirement in 40 CFR 146.86(b)(1). The material selection for packers is Alloy 718 or an equivalent material per 40 CFR 146.86(c)(1).

Corrosion is one of the key factors considered in selecting the tubing, liner, and casing material appropriate for CCS well applications. OLI was utilized to quantify the corrosion rates for carbon steel, corrosion-resistant alloy (CRA), and other materials. This was supplemented by research into current literature, especially experimental work on corrosion in CO_2 rich flow streams. First, water solubility in supercritical (dense phase) CO_2 with and without impurities was established and contextualized to existing literature. Impurities decrease the solubility of water in dense phase CO_2, leading to precipitation of water and creation of a corrosive, low pH aqueous solution saturated with CO_2. Next, corrosion analysis was performed for a wide range of materials in wet

[10] https://olisystems.com

CO_2, using OLI and results from the well performance analysis. With dry injectate (containing less than 500 parts per million H_2O), the corrosion rate is expected to be negligible, however, it is important to consider presence of water during upset conditions. Finally, external corrosion due to exposure to reservoir fluid with wet CO_2 was investigated for a range of mixing conditions. Reservoir saturation as a function of time was used in this analysis. Based on this analysis, it was concluded that modified 13Cr is suitable for CCS injection wells and monitoring wells that are exposed to the reservoir fluids.

Upset conditions were also studied, such as reservoir backflow during shut-in period or reservoir mixing with injection gas at the bottom of the well. Corrosion rates were predicted using a thermodynamic model of a case where injected gas mixes with the reservoir fluid. The reservoir fluid was modeled by using the brine composition listed in **Table 5.2-1** and the gas composition listed in **Table 5.2-2**. The brine and the gas were mixed in the saturator function of OLI at temperature of 241°F and pressure of 4,125 psi. The stream has 69% gas saturation and 31% brine. The resulting mixture was used as the reservoir stream input to the thermodynamic model. The reservoir stream was mixed with pre-combustion stream and post-combustion stream at the following ratios:

- 100 parts injection stream
- 1 part injection stream to 100 parts reservoir stream
- 50 parts injection stream to 50 parts reservoir stream
- 100 parts injection stream to 1 part reservoir stream

The corrosion modeling and results are described in full in **Appendix 5B** and the results are summarized as follows:

- The modeled corrosion rate when the well is shut-in was calculated to be 3.73 mils per year and 1.34 mils per year when the well is injecting. The resulting pH was calculated to be 3.0–3.2.
- The modeled corrosion rates while injecting and while the well is shut-in were used to estimate the remaining body wall for the casing, liner, and tubing at the end of the injection period.
- The remaining body wall results were used to confirm the well can be operated safely throughout the life of the injection period.

The results of the tubular designs are included in the individual well documents in **Appendix 5A**.

5.2.9.2 Materials Summary

A summary of the material planned for the main components for injection and monitoring wells is shown in **Table 5.2-3**.

5.2.9.3 Materials and Manufacturing Standards

Casing, liner, and tubing materials will be manufactured to specifications according to American Petroleum Institute (API) Specification 5CT (API 2018) and American National Standards Institute (ANSI)/API Specification 5CRA (ANSI/API 2021).

Cementing materials will be manufactured to specifications according to API Recommended Practice 10B-2 (API 2013). Pressure containing strings including the casing, liner, tubing, and downhole equipment will have connections manufactured and qualified to API Recommended Practice 5C5 (API 2017).

Packers and liner hanger packers will be manufactured and qualified to API Specification 11D1 (API 2022).

5.2.10 Cementing [40 CFR 146.86(a)(1), 146.86(b)(1), and 146.86(b)(5)]

Sections 5.2.1, 5.2.2 and 5.2.3 discuss the details on construction procedures of new drill wells for injection, repurposed wells for injection, and repurposed wells for monitoring respectively. The placement of casings and liners with the requirement of cement behind the pipe is mentioned within those sections. The following sections from 5.2.10.2 to 5.2.10.5 detail the procedures for placing the cement in stages and elaborate the type of cement with the additives included in its design. It should be noted that the cement design mentioned in sections 5.2.10.2 to 5.2.10.5 are applicable to the new drill wells for CO_2 injection. Whereas the cement design for repurposed wells, corresponding to the well construction procedures included in sections 5.2.2 and 5.2.3, are mentioned in sections 5.2.10.4 and 5.2.10.5 below.

5.2.10.1 Geothermal Temperature Profile

Figure 5.2-3 shows the field geothermal temperature profile vs. TVD used in the analyses for flow assurance modeling, corrosion modeling, well design, and cement slurry design.

5.2.10.2 Surface Casing Cement

The surface casing cement will be circulated to surface to isolate potential USDW zones (40 CFR 146.86[b][2]). Top and bottom wiper plugs will be used to minimize contamination.

Casing will be cemented with a light-weight lead and tail slurries with the top of cement at surface.

Lead Slurry: 12.5 parts per gram (ppg) extended Class G + lost circulation material (LCM) and fluid loss additives.

Tail Slurry: 13.5 ppg extended Class G + LCM and fluid loss additives.

General slurry design comments: The need for accelerators or retarders will be determined during pilot testing. Choice of extender and mix water ratio will consider the minimization of free water. The casing will be centralized to provide 70% or greater stand-off.

Excess slurry volume of 50–100% will be pumped to promote circulation of cement to the surface. The excess will depend on hole conditions specific to the well.

5.2.10.3 Intermediate Casing Cement

Casing will be cemented to surface in two stages with the stage collar at 2,000 ft (40 CFR 146.86[b][4]). The lower stage will be followed by an opening plug to open ports in the stage tool. The upper stage will be cemented and followed by a closing wiper plug to close the ports in the stage tool.

The first (bottom) stage will be cemented with a light-weight lead slurry and standard weight tail slurry.

The second (upper) stage will be cemented with a light-weight slurry with the top of cement at surface.

Stage 1 Lead Slurry: 12.5 ppg extended Class G + LCM and fluid loss additives.

Stage 1 Tail Slurry: 15.8 ppg Class G cement system + LCM and fluid loss additives.

Stage 2 Slurry: 12.5 ppg extended Class G + LCM and fluid loss additives.

General slurry comments: The need for accelerators or retarders will be determined during pilot testing. Choice of extender and mix water ratio will consider the minimization of free water. The casing will be centralized to provide 70% or greater stand-off.

Excess slurry volume of 25% will be pumped for the first stage.

Excess slurry volume of 50–100 % will be pumped for the second stage to promote circulation of cement to the surface. Excess volume will be determined based on hole conditions while drilling.

5.2.10.4 Casing and Inner Casing Cement

The casing will be cemented to surface with a light-weight lead slurry and higher weight tail slurry with the top of cement at surface (40 CFR 146.86[b][3]). Top and bottom wiper plugs will be used to minimize cement contamination.

Lead Slurry: 12.5 ppg extended Class G + LCM.

Tail Slurry: 15.0 ppg CO_2-Resistant cement system + LCM for casing cement.

General slurry comments: The need for fluid loss, retarder, and other additives will be determined as part of the slurry design and during pilot testing. Choice of the extender and mix water ratio will be considered to minimize free water. The casing will be centralized to provide 70% or greater stand-off.

CO_2-resistant cement systems considered for the tail slurry include densified 50:50 fly-ash and Portland cement/silica flour, Portland cement with latex, and proprietary CO_2-resistant blends (40 CFR 146.86[b][5]).

In compliance with 40 CFR 146.86(b)(1)(ix), densified 50:50 fly-ash and Portland cement/silica flour is proposed for the following reasons:

- The reactive Portland cement content is reduced by 50%.

- Exposure to CO_2 is limited to the annular cross-section at the casing shoe (vertical attack) under static conditions.
- Experimental studies showed the alteration front in Portland cement samples exposed to CO_2 saturated water decreased with time over the exposure period of three months (Barlet-Gouedard et al. 2006). The alteration process followed a diffusion law according to e = 0.26 sqrt(time) for wet super critical CO_2 fluid and e = 0.22 sqrt(time) for CO_2 dissolved in water. The approximate alteration rate based on the sample observations was five meters per 1,000 years. The conclusion is that internal and external Portland cement barriers that are tens and hundreds of meters in length will most likely remain effective for many thousands of years based on CO_2 exposure to the cross-section. Furthermore, while CO_2 is contained in the injection zone, the CO_2 is subject to immobilization because of contact with the formation and the reservoir fluids, and the pressure will decrease because of dissipation with time. This indicates that the CO_2 will be permanently sequestered in the reservoir.
- A study was conducted to evaluate cement/pozzolan (fly ash) blend integrity with exposure to CO_2 under sequestration conditions (Kutcho et al. 2009). The conclusion was that cements containing fly ash show improved durability to acid attack.
- Silica flour is included in the design for conditions when temperatures are above 230°F to prevent strength retrogression.

Excess slurry volume of 15% will be used to promote cement circulation to surface for the inner casing long string. The pipe-in-pipe annulus volume can be determined accurately, and the excess volume will provide cement to surface (40 CFR 146.86[b][3]).

Excess slurry volume of 25 – 50% will be used to promote cement circulation to surface for casing set in open hole. An open hole caliper log will be used to estimate the annulus volume and the excess volume will provide cement to surface.

After the long-string inner casing has been cemented, a cement bond and variable density log and a temperature log will be run as required by 40 CFR 146.87(a)(3)(ii) to document an annular seal.

5.2.10.5 Liner Cement

A tail (single) slurry will be used to circulate cement to the top of the liner.

Slurry: light-weight CO_2-resistant cement system.

General slurry comments: managed pressure cementing with foamed water pumped ahead of the slurry to reduce the amount of differential pressure across the depleted 64 Zone Sandstones will be considered based on the actual well conditions. UIC Program Director approval for using managed pressure cementing will be requested.

The liner will be centralized to provide 70% or greater stand-off.

CO_2-resistant cement systems considered include proprietary CO_2-resistant blends, calcium aluminate cement, and resin cements.

In compliance with 40 CFR 146.86(b)(1)(ix), resin cement is proposed for liners for the following reasons:

- No reactive species present (very high CO_2 resistance) (40 CFR 146.86[b][5]).
- More ductile than conventional cements, making it more durable under cyclic loading conditions.
- Can be mixed as light as 9.0 ppg, making a good candidate for cementing the depleted 64 Zone Sandstones.

The planned excess volume is 10–15% for a liner cement job in cased hole and 25–50% in open hole to provide cement circulation to the top of the liner.

A liner top packer will be run to promote liner lap isolation.

After the liner has been cemented, a cement bond and variable density log and a temperature log will be run as required by 40 CFR 146.87(a)(3)(ii) to document an annular seal.

5.2.11 Tubing and Packer Completion

The well will be completed with tubing and a packer per 40 CFR 146.86(c)(2). Materials for the tubing and packer were selected to provide compatibility with the injected and reservoir fluids as required by 40 CFR 146.86(c)(1). The packer will be set in the casing opposite a cemented interval to meet 40 CFR 146.86(c)(2) requirements. The setting depth will be selected based on an evaluation of the cement bond log run after the inner casing is run and cemented. The individual well documents in **Appendix 5A** include the packer load envelope that will be used to select a packer designed to exceed the load envelope.

The tubing sizes for injection wells were selected to inject CO_2 at the planned rates and pressures that are reasonable for surface equipment and facilities.

The tubing size for monitoring wells was selected to allow wireline tools to be run through the tubing for monitoring reservoir conditions as required by CFR 146.90.

5.2.12 Injection and Monitoring Well Casing, Liner, and Tubing Structural Strength Design

The new long-string inner casing, liners, and tubing have been designed to withstand expected loads during the life of the well including the maximum surface pressure loads (40 CFR 146.86[b][1]), and materials selected for these items were based on corrosion analyses so that the materials are compatible with the injected and reservoir fluids per 40 CFR 146.86(b)(1)(ix) and 40 CFR 146.86(c)(1) (see **Tables 5.2-1** and **5.2-2)**. The upper casing section will be carbon steel with a CRA lower section for compatibility with the injected and reservoir fluids. The flow-wetted lower part of the inner casing, liners, tubing, and packer will be CRA materials.

The loads were evaluated and compared to the strengths to select an appropriate well design with safety factors.

The individual well documents in **Attachment K** and **Appendix 5A** include the proposed casing, liner, and tubing design results and safety factor details for each well as required by 40 CFR 146.86 (b)(1) and 40 CFR 146.86(c)(1). The results are for two conditions:

- Design results with no corrosion when the well is repurposed and prepared for injection or monitoring service.
- Design results if there is corrosion and wall loss at the end of service life for wells. The design analysis with corrosion provides confidence that mechanical integrity will be maintained for the life of the well per 40 CFR 146.86(b)(1).

Specifically, casing and cement materials and strengths have been designed and selected to be effective for the life of the Project considering the lithology of the injection and confining zone (40 CFR 146.86[b][1][vii]), and characteristics of the CO_2 stream including quantity, chemical content and composition, temperature, corrosiveness, and density, as well as the formation fluids they will be in contact with, as per 40 CFR 146.86(b)(1)(ix)) and 146.86(c)(3)(ii); see **Sections 2.8.2.2** and **2.8.2.3** for additional details.

5.2.13 Contingency Plans

5.2.13.1 Lost Circulation while Drilling

Drilling in depleted oil and gas fields includes the risk of lost circulation when low pressure production zones are penetrated. Drilling fluid loss rates range from minor losses to total losses. Minor losses can be managed by replenishing the supply of drilling fluid as needed and adding LCM to the fluid system to reduce or eliminate losses. Losses greater than minor losses can be mitigated by spotting fluid pills with high concentrations of LCM, waiting without pumping, and allowing the LCM pills to heal the loss zones. Severe losses to total losses can be treated with plugging materials that bridge and prevent losses. Cement plugs are an option and can be used to regain circulation. If these treatments are not effective, techniques such as managed pressure drilling, aerated fluid, and drilling with foam are options that can be applied.

Dealing with lost circulation while drilling is well understood in the industry and materials, equipment, and procedures are readily available if needed.

5.2.13.2 Lost Circulation while Cementing

Cementing where lost circulation is occurring or is likely to occur is a more challenging problem. Methods to deal with lost circulation while cementing include reduced cement slurry density and modeling to determine if a given slurry design is likely to be placed in the well without losing circulation resulting in a low cement top. Managed pressure cementing, foamed cement, and reverse cementing are technologies that can be implemented to reduce the risk of losing returns while cementing.

Other options include changing the well design to provide cement to surface for the long casing string. This method is proposed for the repurposed wells and new drill wells for this CCS Project, as per 40 CFR 146.86(b)(1)(vii). A long casing string set near the base of the primary confining zone (the Lower Santos) where the open hole fracture strength is sufficient, is proposed to cement

the long string to surface. After the cement is set, the injection zone will be drilled. An injection liner will be run and cemented with the top of the liner extending above the casing shoe. The liner top will be pressure tested to demonstrate mechanical integrity and a liner top packer will be run and set as a secondary seal at the liner top. This design results in a Class VI well design with a long casing string cemented to surface and a cemented liner across the injection zone. The liner overlap will have a primary cemented barrier and a secondary liner top packer barrier to contain the CO_2 within the injection zone.

5.2.13.3 Workover Contingencies

The risk of not being able to clean out a well for repurposing exists. Workovers to clean out wells are routine and contingency planning is part of the planning process. If it is not possible to clean out deep enough in a well and the well is deemed unusable as a repurposed well, steps will be taken to properly abandon the well by setting cement plugs in the previous productive zones to prevent flow of CO_2 or hydrocarbons into unauthorized zones (40 CFR 146.86[a][1]). CO_2-resistant cement will be used as appropriate to prevent the leakage of CO_2 to higher zones including potential USDW zones. The plugging and abandonment procedure will be proposed and approved by the appropriate regulators. Regulatory requirements for plugging and abandoning wells in the AoR will be met.

If workover operations result in an unintended loss of a downhole tool in the well, fishing operations will commence to recover the fish. Steps will be taken to minimize the risk of loss of tools including inspection of equipment and connections prior to running the tools. Fishing operations are common in workover operations and the necessary equipment, services, and expertise to conduct fishing operations are readily available.

5.2.13.4 Drilling Contingencies

Deviation surveys will be taken while drilling new wells. Deviation problems in the North Belridge oil field are not common and are unlikely. The surveys and well path will be monitored while drilling to demonstrate that the final bottomhole location is satisfactory for the well's intended purpose. In the unlikely event the surveys show the borehole has unplanned excess deviation, the hole will be plugged back and redrilled.

If the drill string parts and a fish is left in the well, fishing operations will commence to recover the fish. The risks of not recovering fish are low and normal drilling operations will continue after the fish is recovered. In the unlikely event the fish cannot be recovered, appropriate steps will be taken to properly plug the open hole with cement to prevent migration of CO_2 and hydrocarbons to unauthorized zones.

Well control is not likely to be a problem while drilling because of the past production that has depleted the oil and gas zones. Drilling fluid returns will be monitored while drilling to check for fluid gains or losses. If either is observed, the well will be monitored to determine the status and steps will be taken to get the well back into a condition to resume drilling. If a fluid gain was detected, normal well control procedures will be conducted to circulate out the influx and the mud weight will be adjusted as required to resume safe operations. Fluid losses were discussed in a previous section.

6. PRE-OPERATIONAL LOGGING AND TESTING

The CarbonFrontier Pre-Operational Well Testing Plan pursuant to 40 CFR 146.82(a)(8) and 146.87 describes existing data for the North Belridge oil field and supplemental logging and testing to be performed for both new and repurposed injection wells. The Pre-Operational Well Testing Plan is included as **Attachment D**.

Pre-Operational Logging and Testing GSDT Submissions
GSDT Module: Pre-Operational Testing ***Tab(s):*** Welcome tab Please use the checkbox(es) to verify the following information was submitted to the GSDT: ☒Proposed pre-operational testing program ***[40 CFR 146.82(a)(8) and 146.87]***

7. WELL OPERATION

7.1 Operational Procedures [40 CFR 146.82(a)(10)]

Operational procedures were derived from the following reservoir and well characteristics:

- Depth of the injection and confining intervals (**Sections 2.2** and **2.4**)
- Permeability and thickness of the injection zone (**Sections 2.4** and **2.5**)
- Geomechanical properties and fault analysis (**Sections 2.5** and **2.3**)
- Well construction (**Section 5**) for the tubing design and characteristics of the pipe

A 1D wellbore PROSPER model, calibrated to field data and presented in the "site suitability" section (**Section 2.10**)**,** was used to determine the operation procedures proposed in **Table 7.1**. The model is based on a discretized wellbore and considers thermal effects, friction, and multiphase-multi components thermodynamical properties using a Peng-Robinson (1976) equation of state. It can predict CO_2 conditions and rates from surface to bottom-hole for various reservoir characteristics and pressures.

Many of the proposed operating parameters will vary during the life of the Project. The "minimum annulus pressure/tubing differential" can be chosen and potentially kept fixed by design. The depth of the top of the perforations isn't expected to be modified. Localized effects with faults within the AoR (**Table 2.3-2**) will be monitored during injection and operating parameters will be adjusted as needed. Maximum injection rates are expected to be achieved while reservoir pressure is the lowest (on wells with the best injectivity and lowest skin) and will tend to decline afterwards due to reservoir re-pressurization and limitations due to surface constraints. Lower reservoir pressure may require the rates to be constrained due to increased effective stress that can occur at lower pore pressure on wells with the poorest injectivity. In essence, the surface constraints, well head rates, and pressure/temperature will have to be modified to adapt to downhole conditions.

Aera will gather testing and monitoring data prior to (**Attachment D**) and during the injection operations (**Attachment E**) to adapt and update operational parameters and continuously meet requirements of 40 CFR 146.88.

7.1.1 Injection Well Operating Requirements [40 CFR 146.88]

Proposed operational parameters are designed to operate below the 80% fracture pressure of the injection or confining zones and pressure will be monitored continuously to comply with 40 CFR 146.88(a).

Injection will occur through a CO_2-compatible tubing string to comply with 40 CFR 146.88(b).

Other than during periods of well workover (maintenance) approved by the UIC Program Director in which the sealed tubing-casing annulus is disassembled for maintenance or corrective procedures, Aera will maintain mechanical integrity of the injection wells to meet the requirements of 40 CFR 146.88(d).

Aera will install devices to continuously monitor operational parameters, as discussed in **Section 5** and **Attachment E**, to fulfill the requirements of 40 CFR 146.88(e)(1).

Aera will install and use alarms and automatic surface shutoff systems to meet the requirements of 40 CFR 146.88(e)(2), as described in **Section 5**.

7.1.2 Shutdown or Mechanical Integrity Loss [40 CFR 146.88(f)]

If a shutdown is triggered or a loss of mechanical integrity is discovered, Aera will immediately investigate and identify, as expeditiously as possible, the cause of the shutoff. If, upon such investigation, the well appears to be lacking mechanical integrity, or if monitoring required under 40 CFR 146.88(e) otherwise indicates that the well may be lacking mechanical integrity, Aera will perform the following:

1. Notify the UIC Program Director within 24 hours of the event.
2. Initiate shutdown plan, in consultation with the EPA UIC Program Director.
3. Notify Belridge Producing Complex, On Duty Manager of Operations and/or On Duty Supervisor (s), using the Aera Pre-Incident Plan for Emergency Response as applicable.
4. Initiate the Incident Command System and begin staffing an Incident Management Team.
5. Use handheld equipment to measure CO_2 levels, then isolate and restrict access as appropriate to the CarbonFrontier site.
6. Continuously monitor the well site, well pressure, temperature, and annulus fluid level and annulus pressure to assess integrity loss and determine the root cause of failure.
7. Perform appropriate repairs and confirm internal and external mechanical integrity prior to restarting injection upon approval from the UIC Program Director.
8. Monitor CO_2 and indicator parameter levels, as appropriate in groundwater monitoring wells.
9. Based on analytical results and observations, a case-specific work plan may be developed in consultation with the UIC Program Director and may include, but not be limited to, additional groundwater monitoring and evaluation of further actions.
10. Notify the UIC Program Director when injection can be expected to resume.

Additional details on mechanical integrity loss severity, timing, avoidance measures, detection methods, response personnel, and equipment are in the Emergency and Remedial Response Plan (**Attachment I**).

7.2 Proposed Carbon Dioxide Stream [40 CFR 146.82(a)(7)(iii) and (iv)]

The proposed CO_2 stream will be sourced from a mixture of Aera's planned CO_2 capture facilities, located in the adjacent South Belridge oilfield, and, at a time and from a source unknown at this time, from third-party suppliers, received by pipeline or truck. The CO_2 stream's estimated

composition was presented in **Section 2.8.2.3** and **Table 2.8.3** of the geochemical work from the site characterization. Aera plans to construct facilities that will capture CO_2 from produced natural gas (pre-combustion) and from the flu gas of steam boilers and cogeneration units (post-combustion). Pre-combustion CO_2 volumes are estimated to total approximately 0.3 MM mt/yr, while post-combustion sources are expected to yield up to 1.3 MM mt/yr. Construction of these facilities, pending regulatory approvals discussed in **Section 1**, will begin in 2024 or 2025. Therefore, a CO_2 sample cannot yet be obtained. The planned facilities will utilize commercially available amine-based technologies to capture CO_2, which will allow for confident estimates of the CO_2 stream composition based on industry analogs and will be tailored to the input gas stream compositions.

In addition to the pre- and post-combustion sources discussed above, the Project will be designed to receive up to 1.7 MM mt/yr of outside CO_2 sources, delivered by pipeline and truck. The total volume of CO_2 received, including both Aera and third-party sources, will not exceed the total proposed injection volume (**Table 7.1**). Although no third-party CO_2 suppliers are committed at this time, a CO_2 composition specification for future CO_2 sources has been established to fulfill the requirements of 40 CFR 146.82(a)(7)(iii) and (iv). Future sources of CO_2 will meet the composition limits established in this spec. The CO_2 composition specification closely matches the composition of Aera's proposed sources and is not anticipated to have material impacts on the overall CO_2 stream composition (**Table 7.2**).

CO_2 sources, from Aera's facilities or third-party sources received by truck and pipeline, will be tested according to the requirements of 40 CFR 146.90(a) and reported to EPA according to the requirements of 40 CFR 146.82(a)(7)(iv). Third-party sources will enter Aera's CO_2 pipeline sufficiently upstream of sampling, testing, and monitoring locations to allow for representative results to be achieved.

Corrosiveness of the CO_2 stream and estimated impact on the wells materials and cement are presented in **Section 5**.

Reactivity with the injection formation, fluids or confining layer was studied in the geochemical section of the site characterization (**Section 2.8**) and is expected to have minimal effects on the permeability, porosity and injectivity.

The CO_2 stream will behave according to the laws of thermodynamics. Due to the highly compressible nature of CO_2 for various pressures and temperatures, the behavior of the CO_2 stream will vary greatly over the lifetime of the Project. Initial reservoir conditions might require lower downhole pressure and gas phase injection while later life injection will require higher surface and bottom-hole pressure to support injection in super-critical and denser phase. Pressure increase will tend to make the CO_2 stream denser while the downhole heat and reservoir conditions will tend to warm the stream and lower the density. Pressure and temperature of the CO_2 will be monitored closely as sudden density changes can result in rapid bottom-hole pressure changes.

8. TESTING AND MONITORING

The CarbonFrontier Testing and Monitoring Plan pursuant to 40 CFR 146.82(a)(15) and 146.90 describes the strategies for testing and monitoring to demonstrate injection wells are operating as planned, document injection well mechanical integrity, monitor CO_2 plume and pressure front, and demonstrate non-endangerment of USDWs. The Testing and Monitoring Plan is included as **Attachment E**.

Agency/Jurisdiction	Permit(s)/Act/Consultations	Authority	Status*
Federal Consultations			
U.S. Environmental Protection Agency (EPA) – U.S. Fish and Wildlife Service Interagency Consultation	Endangered Species Act (ESA) Section 7 Consultation	16 USC 1513 50 CFR Section 17	A Biological Assessment (BA) was submitted to EPA in December 2023.
EPA – State historic Preservation Officer Interagency Consultation	National Historic Preservation Act (NHPA) Section 106 Consultation with SHPO	National Historic Preservation Act 36 CFR 800	A cultural resources inventory was submitted to EPA in July 2023.
EPA	Hazardous Waste Permit	Resource Conservation and Recovery Act (RCRA)	Aera intends to pursue a RCRA exclusion in compliance with the conditions specified under 40 CFR 261.4(h)
U.S. Department of Transportation, Pipeline and Hazardous Materials Safety Administration (PHMSA)	CO_2 Pipeline Approval	49 CFR Part 195	Applicability is to be determined.
Caltrans	Right-of-Way Encroachment Permit for Transportation of Oversized Loads	Caltrans Project Development Procedures Manual	Applicability is to be determined.
State and Local Consultations			
Kern County Planning and Natural Resources Department	Conditional Use Permit (CUP) Zone Change (ZC)	County Code/CEQA	CUP/ZC Application Deemed Complete 9/26/2022
Kern County Public Works Department	Building Permit, Grading Permit Encroachment Permit	County Code	Applicability is to be determined
Kern County Fire Department	Approval of Fire Safety Plan	Fire Code	The project applicant plans to consult with the Kern County Fire Department
San Joaquin Valley Air Pollution Control District (SJVAPCD)	Title V Authority to Construct (ATC)/Permit to Operate (PTO)	Clean Air Act Regulation VIII – Fugitive PM10 Prohibitions	The project applicant anticipates submitting an ATC application in 2024
	Approval of Fugitive Dust Control Plan		The project applicant plans to consult with the SJVAPCD
	Clean Air Act - New Source Review (NSR). The project is subject to NSR preconstruction authorization.		The project will be subject to a New Source Review (NSR) and will comply with requirements under Prevention of Significant Deterioration (PSD) program and/or the Nonattainment NSR program. The project applicant is evaluating which of these programs will apply.
California Department of Fish and Wildlife (CDFW)	Incidental Take Permit Application (ITP)	California Fish and Game Code – Section 2081	The project applicant is consulting with CDFW regarding the need for an ITP and anticipates submitting an application in 2024.
Regional Water Quality Control Board (RWQCB)	National Pollutant Discharge Elimination System (NPDES) Construction Permit Storm Water Permit General Waste Discharge Requirements Enrollment for Impacts to Waters of the State	Clean Water Act Porter-Colone State Water Quality Act	Applicability is to be determined.
California Air Resources Board (CARB) – LCFS Permanence Certification	Sequestration Site Certification	17 CCR Sections 95480-95503	The project applicant submitted an application for Sequestration Site Certification in December 2023.
	CCS Project Certification		The project applicant anticipates submitting a CCS Project Certification application in 2025/2026.
California Public Utilities Commission (CPUC)	Permit to Construct	CEQA Public Utilities Code Sections 1001 et seq. CPUC General Order 131-D	Applicability is to be determined.
California Geologic Energy Management Division (CalGEM)	Consultation/approval for CO_2 Pipeline	California Statutes and Regulations for Conservation of Oil, Gas, and Geothermal Resources (January 2022) Senate Bill 1137	Applicability is to be determined.
Office of the State Fire Marshal (OSFM)	Consultation/approval for CO_2 Pipeline	49 CFR Part 195 The Elder California Pipeline Safety Act	Applicability is to be determined.
California Natural Resources Agency	Consultation/approval for CO_2 Pipeline	SB 905	Applicability is to be determined.

*As of [03/06/2023]

Table 2.3-1: Fault Inventory Summary
Site Characterization
Faults and Fractures

Fault Name	Sense of Slip	Strike/Dip (°) and Dip Direction	Length	Vertical Extent	Seismic Vertical Offset in 64 Zone (minimum; maximum)	Geologic Model Vertical Offset in 64 Zone (minimum; maximum)	Transect Injection Zone	Transect Confining Zone	Lateral Confinement
East Bounding Thrust Fault	Listric Thrust; Reverse	130/35 SW	>8 miles	Reef Ridge Member of the Monterey Fm (average depth of 4500 ft TVDss)	~500 ft in central portion of AoI (NE Section 27) to >700 ft in the southern portion of AoI	~300 ft in central portion of AoI (NE Section 27) to >700 ft in the northern and southern portions of AoI	Yes	Yes	Unknown
West Bounding Thrust Fault	Back Thrust; Splay from East Bounding Thrust Fault	330/40-45 NE	>7 miles	Upper Reef Ridge Member of Monterey Fm (average depth 2500 ft TVDss)	~200 ft in central portion of AoI (SW Section 35) to >300 ft in southern most portion of AoI	<100 ft in northern and southern portions of AoI to >400 ft in central portion of AoI (SW Section 35)	Yes	Yes	Possibly; Yes north of Downdip West Flank Cross Fault
MB13	Scissor Fault; Change in apparent vertical offset from normal to reverse from south to north	180/75 W	~3 miles	Etchegoin Fm (average depth of 2000 ft TVDss)	100-150 ft in the northern portion of fault to 200-300 ft in the southern and central portions of the fault	~250 ft in the northern portion of fault to >400 ft in the southern and central portion of the fault	Yes	Yes	Yes (**Figure 2.3-10**)
Downdip West Flank Cross Fault	Reverse	255/80 NW	~1.5 miles	Upper Santos Shale in the Temblor Fm (average depth of 6000 ft TVDss)	0 ft in western extent (Section 29) to 250-300 ft in the eastern and central portion of the fault (Sections 27 and 28)	0 ft in western extent (SW corner Section 28) to 200 ft in the central portion of the fault (SE Section 28)	Yes	Yes	Unknown, outside AoR
Southern Crestal Fault	Reverse	145/80 SW	~1-1.5 miles	Media Shale Member in the Upper Temblor Fm (average depth of 5500 ft TVDss)	50-100 ft in the eastern portion of Section 35 to 150-200 ft in southern and central portions of the fault (Section 36)	<50 ft in the central fault (SW Section 36) to 100-150 ft in southern end of fault (N Section 1)	Yes	Yes	No
West Limb Thrust Fault	Thrust; Subsidiary fault to West Bounding Thrust Fault, Splay from East Bounding Thrust Fault	315/35 NE	~2 miles	Santos Shale Member of the Temblor Fm (average depth of 6800 ft TVDss)	50-100 ft to NE to 200 ft to the SE	50-100 ft to SE to 150 ft to the NW	Yes	Yes	No
Northern Crestal Fault (1)	Reverse; Splays off of West Limb Thrust Fault	130/70 SW	~1 mile	Media Shale Member in the Temblor Fm (average depth of 6000 ft TVDss)	50-100 ft in the NW portion of fault (Section 22) to 100-150 ft in the central portion of the fault (Section 27)	0 ft in the northern portion of fault (Section 22) to ~150 ft in the southern portion of the fault (Section 27)	Yes	Yes	No
Northern Crestal Fault (2)	Normal	240/85 NW	~1 mile	Media Shale Member in the Temblor Fm (average depth of 6000 ft TVDss)	<50 ft towards eastern potion of fault (Section 22) to 100 ft in the southern and central portions of the fault (Section 28)	~50 ft in the central potion of fault (Section 22) to 75-100 ft in the SW and NE portions of the fault	Yes	Yes	Possibly (**Figure 2.3-9**)
MB12	Obilque Right-Lateral Reverse; Subsidiary fault to MB13	200/75 NW	~1 mile	Etchegoin Fm (average depth of 2000 ft TVDss)	<50 ft in the northern extent (terminates in southern half of Section 1) to 50-150 ft in the southern and central portions of the fault	0 ft in the southern extent of the fault to ~250 ft in the central portion of the fault (center Section 12)	Yes	Yes	No
Central Crestal Fault (1)	Reverse	110/85 SW	~0.5 miles	Media Shale Member in the Upper Temblor Fm or Lower Monterey Fm (average depth of 6000 ft TVDss)	~150 ft in southern portion of fault	~50 ft in central portion of fault	Yes	Yes	No
Central Crestal Fault (2)	Normal; Splay off the West Limb Thrust Fault	080/85 SE	~0.5 miles	Media Shale Member in the Upper Temblor Fm or Lower Monterey Fm (average depth of 5000 ft TVDss)	50-100 ft	<50 ft	Yes	Yes	No
Northern Crestal Fault (3)	Normal; Splay off the West Limb Thrust Fault	125/85 SW	~0.5 miles	Upper Santos Shale in the Temblor Fm (average depth of 6000 ft TVDss)	50-100 ft from SW to NW	<50 ft	Yes	Yes	Unknown, outside AoR

Notes:
° - degrees
Strike notation is reported in azimuth convention (degrees) and follows the right-hand rule
Dip is reported as a dip angle (in degrees) and dip direction
ft - feet
TVDss - True Vertical Depth below mean sea level
AoI - Area of Interest
AoR - Area of Review

Notes:

1) Breitburn Operating LP., 2018a, Groundwater Monitoring Report for Post Stimulation Treatments and Requests for Exclusion, Dow Chanslor Lease, North and South Belridge Fields, Kern County, California, GeoTracker Site Global ID: GAOG10010818. June 22.
2) Wood Environmental & Infrastructure Solutions, Inc., 2021, 2021 Annual Post Closure Maintenance and Monitoring Report – Former North Surface Impoundments, North Belridge Oil Field, Kern County, California, GeoTracker Site Global ID: SL0602993186. December 16.
3) Wood Environmental & Infrastructure Solutions, Inc., 2022, Revised Second Semiannual 2021 SB4 Groundwater Monitoring Report – Section 12, 13, and 18 Leases, South Belridge Oil Field, Kern County, California, GeoTracker Site Global ID: GAOG10009277. February 28.
4) Groundwater and Environmental Services, Inc., 2022, Third Quarter 2021 SB4 Post Well Stimulation Groundwater Monitoring Report, South Belridge Oil Field, Hill Lease, Kern County, California, GeoTracker Site Global ID: GAOG10011328. June 10.
5) Duplicate result reported if TDS concentrations were higher than original sample.
6) Analytical results for TDS and/or EC were not consistent with historical values. Calculated TDS values for wells 26A1 and 276(2)-26 are 30,000 and 33,000 mg/L, respectively.

Coordinates provided in NAD 1983 State Plane California V FIPS 0405 (US Feet)
ft msl- feet above mean sea level
ft bgs - feet below the ground surface
ft btoc- Depth to groundwater measured in feet below top of casing
TDS - total dissolved solids
mg/L - milligrams per liter
* MW-01, MW-04, MW-08, MW-09, and MW-12 depth to ground water measured in ft bgs

Notes:
Some results from Well 43-27N were obtained via X-ray diffraction (XRD) analysis. Analysis completed in October 1985 by Haliburton Chemical Research and Development Department.
All other results were obtained by point-counting petrographic thin sections. Analysis completed in September 1986 by Petroleum Testing Services.
Point-counting results provided in % of minerals observed
XRD results provided in mineral weight %.
Specifics regarding point-counting methodology and XRD instrumentation settings were not provided in results reports.
ft - feet

H_2O	ppm	<258	<258	<100	89.5
H_2	%	0	0	<1	0.26

Notes:
ppm - Parts per million

Injectate composition is expected to consist of roughly 50% Aera Sources (comprised of 17% Pre-Combustion product and 83% Post-Combustion product) and 50% Third-Party sources.

* : The characterization of sulfur is inclusive of a variety of sulfur-containing compounds which are expected to occur in the pre-combustion and Third-Party injectate streams in small quantities.

All concentrations are reported on a volume basis except lubrication oils, sulfur-containing compounds, and H_2O, which are reported in concentrations by mass.

Expected injectate components were calculated using the source fractions mentioned above by averaging minimum and maximum concentrations from ranges. Component percentages may not be exact, as many chemicals are provided as ranges or upper limits only.

Mineral	Idealized Mineral Formula	Molar Mass (g/mol)	Normalized Mineral Abundance (%)	Model Input (mol/L)
Quartz	SiO_2	60.08	60.24	26.57
K-Feldspar	$KAlSi_3O_8$	278.3	20.15	1.92
Plagioclase	$NaAlSi_3O_8$	262.2	12.37	1.25
Dolomite	$CaMg(CO_3)_2$	184.4	0.72	0.104
Calcite	$CaCO_3$	100.1	0.52	0.138
Kaolinite	$Al_2Si_2O_5(OH)_4$	258.2	2.40	0.246
Illite	$K_{0.6}Mg_{0.25}Al_{1.8}Al_{0.5}Si_{3.5}O_{10}(OH)_2$	389.3	2.88	0.196
Smectite	$Ca_{0.02}Na_{0.15}K_{0.2}Fe^{++}_{0.29}Fe^{+++}_{0.16}Mg_{0.9}Al_{1.25}Si_{3.75}H_2O$	549.1	0.51	0.025
Glauconite	$(K,Na)(Fe,Al,Mg)_2(Si,Al)_4O_{10}(OH)_2$	426.9	0.16	0.010
Anhydrite	$CaSO_4$	136.1	0.06	0.012

Notes:
Mineral formulas displayed are idealized formulas and represent the stoichiometry utilized in model calculations
Mineralogy results from point-counting analyses were normalized to 100% to remove the presence of porosity and rock fragments
g/mol - grams per mole
mol/L - moles per liter of specified mineral

Table 2.8-5: 64 Zone Sandstone Aqueous Geochemistry Input for Geochemical Modeling
Site Characterization
Geochemistry

Parameter	Unit	Model Input
Calcium	mg/L	728
Magnesium	mg/L	88.2

CH_4	96.013

Notes:

% = milligrams per liter
N = Nitrogen
O = Oxygen
H = Hydrogen
C = Carbon
S = Sulfur

Table 5.2-3: Summary of Materials for Injection and Monitoring Wells
Injection Well Construction
Construction Procedures

Well Type	Components	Recommended Material
Injection	Flow wetted wellhead components (tree valves, flow cross, tubing hanger, etc.)	F6NM-Grade Stainless Steel
Injection	CRA material for tubing, casing, and liners	Modified 13Cr
Injection	Packer and downhole components	Alloy 718
Monitoring	Flow wetted wellhead components (tree valves, flow cross, tubing hanger, etc.)	F22 with Alloy 625 Clad
Monitoring	CRA material for tubing, casing, and liners	Modified 13Cr
Monitoring	Packer and downhole components	Alloy 718 or equivalent
Injection and Monitoring	Elastomer for tubing hanger seals(1)	HNBR/Teflon/PEEK
Injection and Monitoring	Elastomer for packer element(1)	EPDM
Injection and Monitoring	Elastomer for other downhole seals(1)	HNBR/Teflon/PEEK

Notes:
CRA - Corrossion-resistant alloy
13Cr - 13Cr-grade stainless steel
F22 - F22-grade stainless steel
HNBR - Hydrogenated nitrile butadiene rubber
PEEK - Polyether ether ketone
EPDM - Ethylene propylene diene monomer rubber
1) All seals should be evaluated for rapid gas decompression (RGD) capability.
No chemical reaction is expected for this type of material with dense phase CO2.

Table 7.1: Proposed Operation Procedures
Well Operation

Parameters/Conditions	Unit	Limit or Permitted Value								
		27R-27N	55-26N	64-35N	9-1N	64-27N	CI1-64Z-27N	CI2-64Z-35N	CI3-64Z-35N	CI4-64Z-35N

* variable, maintained at the largest of hydrostatic pressure and (tubing bottom hole pressure + 100 psi)
psi: pounds per square inch
psia: pounds per square inch absolute
MMt: million metric tons
Bcf: billion cubic feet

Table 7.2: Estimated CO_2 Composition of Aera's Planned Pre- and Post-Combustion CO_2 Capture Facilities
Well Operation

Chemical	Unit	CO_2 Stream Components		
		Aera Pre-Combustion	Aera Post-Combustion	Third-Party Spec
CO_2	%	95-99.9	98-99.9	>95
CH_4	%	0.05-2	0	<1
C_2	%	0.02-1	0	<1 combined
C_3	%	0.03-1	0	
C_4	%	0.02-1	0	
C_5+	%	0.01-0.5	0	
Lubrication Oils	ppm	5-10	5-10	<20
N_2	%	0-0.05	0-0.05	<0.05
O_2	ppm	<50	<50	<50
CO	ppm	0	<100	<100
NO_x	ppm	0	<150	<150
SO_2	ppm	0	<10	<20
NH_3	ppm	0-10	0-10	<10
H_2S	ppm	2-10	0	<40
Sulfur*	ppm	3-30	0	<16
Ar	ppm	0	0-10	<10
H_2O	ppm	<258	<258	<100
H_2	%	0	0	<1

Notes:
ppm - Parts per million
Values calculated using industry analogs with representative input gas streams.
A third-party spec was established to restrict the composition of all future CO_2 sources and closely aligns with the composition of Aera sources. All concentrations are reported on a volume basis except lubrication oils, sulfur, and H_2O, which are reported in concentrations by mass .
Injectate composition is expected to consist of roughly 50% Aera Sources (17% Pre-Combustion and 83% Post-Combustion) and 50% Third-Party.
* : The characterization of sulfur is inclusive of a variety of sulfur-containing compounds which are expected to occur in the Pre-Combustion injectate stream at small quantities.

Legend

- Project Location
- San Andreas Fault
- San Joaquin Basin
- Quaternary marine and nonmarine sand deposits
- Quaternary alluvium, lake, playa, and terrace deposits
- Pliocene and/or Pleistocene sandstone, shale, and gravel deposits
- Pliocene sandstone, siltstone, shale, and conglomerate
- Miocene sandstone, shale, siltstone, conglomerate, and breccia
- Eocene shale, sandstone, and conglomerate
- Latest Cretaceous and Paleocene sandstone, shale, and conglomerate
- Tertiary volcanic rocks
- Upper Cretaceous sandstone, shale, and conglomerate
- Lower Cretaceous sandstone, shale, and conglomerate
- Franciscan Complex
- Jurassic shale, sandstone, and other rocks
- Mesozoic to Precambrian granitic and metamorphic rocks
- Undivided mesozoic volcanic and metavolcanic rocks
- Undivided pre-Cenozoic metavolcanic rocks
- Mesozoic granite and other plutonic rocks
- Ultramafic rocks, mostly serpentine, chiefly Mesozoic
- Gabbro and dark dioritic rocks, chiefly Mesozoic
- Undivided Paleozoic metasedimentary rocks
- Undivided pre-Cenozoic metasedimentary and metavolcanic rocks

Legend

- Gamma Ray
- Deep Resistivity
- Bulk Density
- Neutron Porosity

Predicted Lithofacies

- Mudstone
- Silty Sand
- Sand
- Cemented Interval
- Undifferentiated

Unit

- Carneros Shale
- Lower Carneros Sandstone
- Upper Santos Shale
- Agua Sandstone
- Lower Santos Shale
- U Sandstone
- U Shale
- W Sandstone
- Salt Creek Shale
- Gibson Sandstone
- Tumey Shale
- Oceanic Sandstone
- Kreyenhagen Shale

Explanation

TVD = True Vertical Depth
GR = Gamma Ray Log
gAPI = API gamma ray unit
TVDss = True vertical depth sub sea (ft)
ft = feet
DRES = Deep Resitivity
ohm.m = ohm-meter
RHOB = Bulk Density
g/cm³ = grams per cubic centimeter
NPHI = Neutron Porosity
ft³/ft³ = cubic ft per cubic ft
Lith = Lithofacies prediction from well log modeling

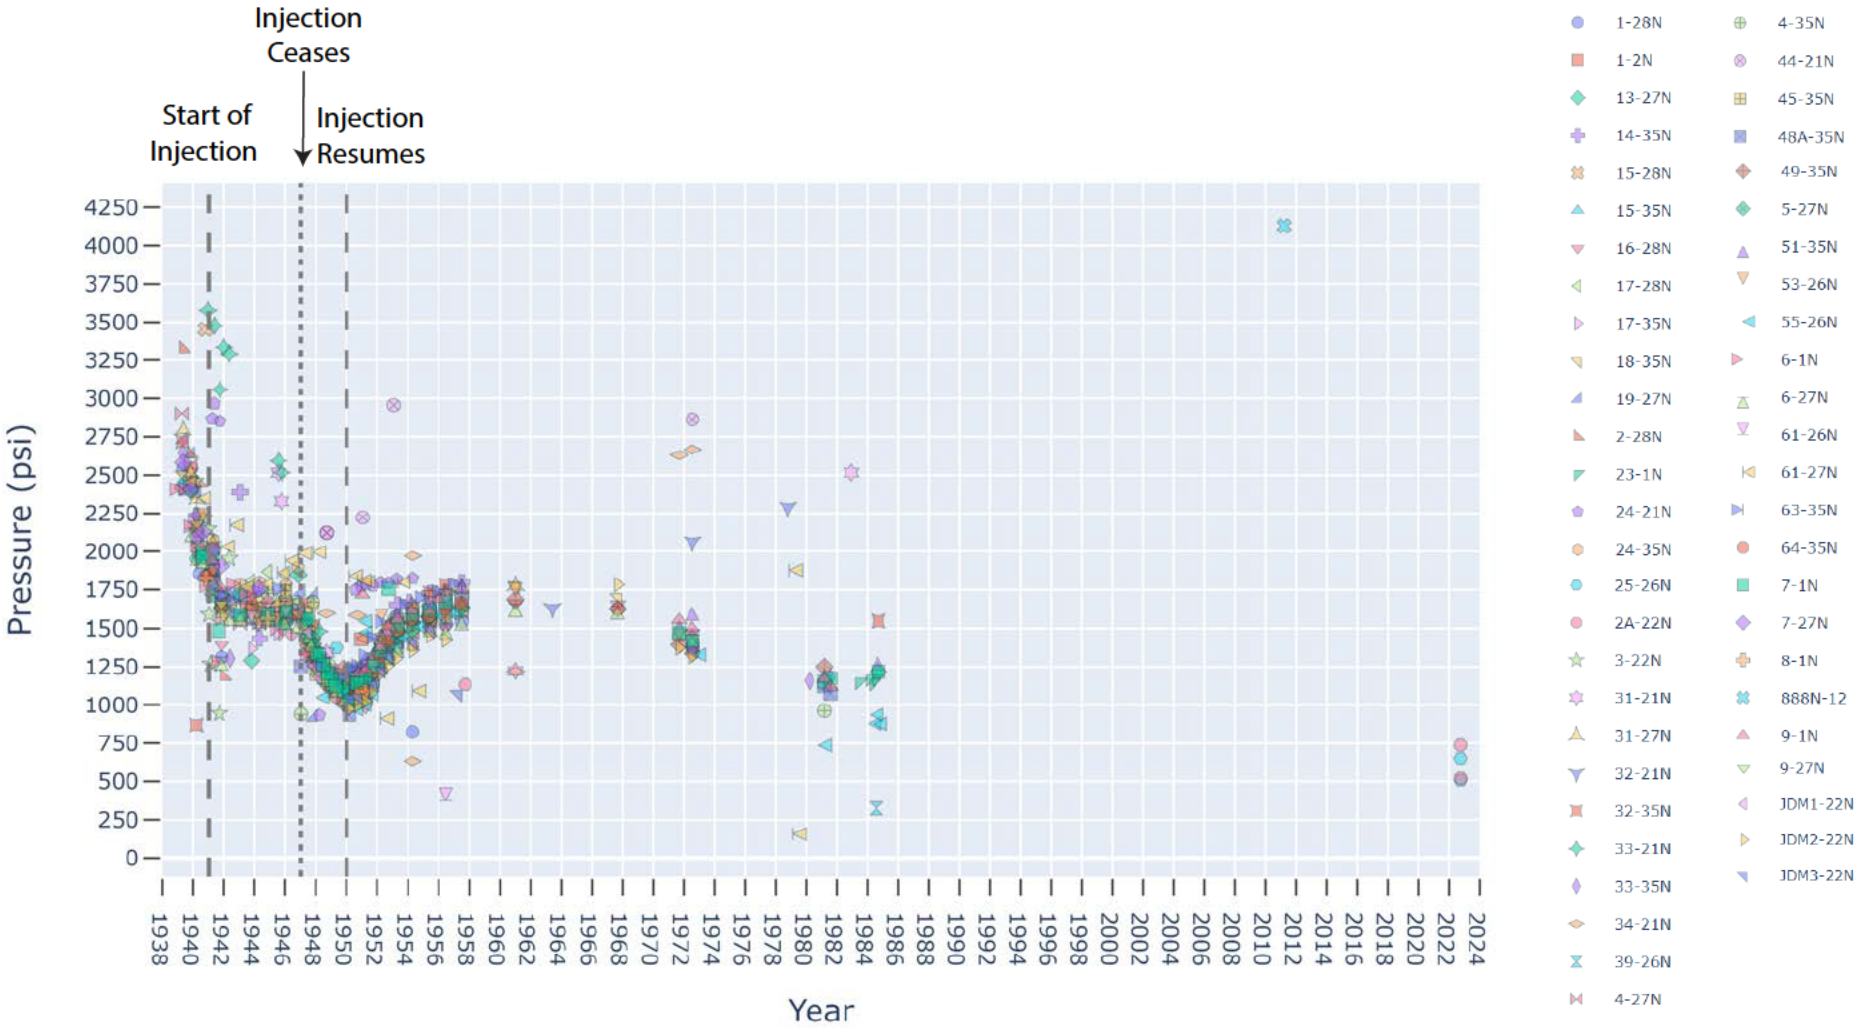
Wells with Pressure Data from 64 Zone Depth to Top U Sandstone



North Belridge Oil Field
Western Kern County
California

Geosyntec consultants

CarbonFrontier	December 2023

Figure 2.3-7

Geosyntec\Aera Belridge CCUS Project - General\EPA VI\A. Technical\01_Figures_EPAResponse202312\i_Illustrator\Narrative_ Fig2.3-7 Wells with 64 Zone Pressure Data - Top of U.ai

Notes:

- 64 Zone pressure data was normalized to a reference depth of 7,700 ft TVDss and an oil gradient of 0.312 psi/ft, after Kaczorowski et al. (1986).
- Historic pressure data from all wells from throughout the proposed injection zone are shown, irrespective of position within Area of Review or fault block.
- Gas injection into the main fault block (Area of Review) began in 1941, ceased in the late 1940's and resumed in 1950.

Explanation:

-psi - pounds per square inch

Geosyntec\Aera Belridge CCUS Project - General\EPA VI\A. Technical\01_Figures_EPAResponse202312\i_Illustrator\Narrative_ Fig2.3-8 64 Zone Pressure Data.ai

Notes:

- 64 Zone pressure data was normalized to a reference depth of 7,700 ft TVDss and an oil gradient of 0.312 psi/ft, after Kaczorowski et al. (1986).
- Gas injection south of the Northern Crestal Fault (2) into the 64 Zone began in 1941,ceased in the late 1940's and resumed in 1950. No injection activities occurred in the northern fault block (i.e., north of Northern Crestal Fault (2)).
- Wells with yellow symbols are located to the north of Northern Crestal Fault (2), whereas wells with blue symbols are located to the south of the fault within the Area of Review.

Explanation:

-psi - pounds per square inch

Geosyntec\Aera Belridge CCUS Project - General\EPA VI\A. Technical\01_Figures_EPAResponse202312\i_Illustrator\Narrative_ Fig2.3-9 Pressure Differentials North Crestal Fault (2).ai

Notes:

- 64 Zone pressure data was normalized to a reference depth of 7,700 ft TVDss and an oil gradient of 0.312 psi/ft, after Kaczorowski et al. (1986).
- Wells 23-1N and 888N-12 are located directly adjacent to the MB13 Fault, whereas 2A-22 and 25-26N are in the northern portion of the Area of Review.
- Pressure measurements collected in 2022 from wells 2A-22N and 25-26N are inferred to be representative of current pressure conditions throughout the Area of Review.

Figure
2.8-1

CarbonFrontier | December 2023

Legend:

1 2 3

1 = uncemented wet sand
2 = sand with residual oil
3 = cemented sand

Explanation:

v/v = pore volume/total volume
ohm.m = ohm-meter

Notes:

1. The cementation exponent value used to construct the Pickett plot (slope of the line) was 1.9, which is the mean value of measurements on seven samples from well 17-2N.
2. The formation water resistivity at Gump Trust 30-1 was estimated at approximately 0.1 ohm-meters by extrapolating the blue line to a porosity of 1 (all fluid).

Notes:
1. Coordinates provided in NAD 1927 State Plane California V
--: data not available
Delta MD: Difference in MD from top well pick to base well pick (well based)
Delta Z: Difference in TVDss (Z) from top well pick to base well pick (well based)
MD: measured depth
NAD 1927: North American Datum of 1927
TST Model: True stratigraphic thickness from the model is calculated by projecting a right angle of a point on surface 1 to the underlying surface 2.
The surfaces are generated from well picks and seismic data prior to thickness calculations.
TVDss: true vertical depth subsea
TVT Model: True vertical thickness calculated from the model using the Z location of surface 1 minus the Z location of surface 2.
The surfaces are generated from well picks and seismic data prior to thickness calculations.
UWI: Unique Well Identifier
X: Easting
Y: Northing
Z: True vertical depth subsea level (feet)

Notes:
1. Surface and bottom-hole coordinates provided in NAD 1927 State Plane California V
MD: measured depth (feet)
TD: Total depth
TVDss: True Vertical Depth sub sea level (feet)

Appendix 2B
Maps and Cross Sections of the AoR Supporting Data

Wells Tops for Geologic Model and Map

Legend:

- Area of Interest
- Township/Range Boundaries
- Section Boundaries
- 1973/74 Oil Field Boundaries
- Fault Traces
- Elevation Contours (500 ft CI)
- Area of Review
- Anticline Axis

Explanation:

ft - feet
TVT - true vertical thickness
CI - contour interval

Notes:

Surface artifacts due to interpolation across faults and structural model grid.

True Vertical Thickness of 64 Zone and Wells for Geologic model

North Belridge Oil Field
Western Kern County
California

Geosyntec consultants

CarbonFrontier | December 2023

North Belridge Structural Model and Property Modeling

Introduction

The following document describes the structural framework and geocellular grid models used to represent subsurface conditions based on seismic interpretation, well picks, well logs, and core analyses. The workflows were preformed in SLB's Petrel™ software.

Fault Framework

The fault framework for the North Belridge study area consists of 12 faults which were interpreted on the three-dimensional (3D) seismic. A brief overview is given below. The faulting is discussed in detail in **Section 2.3.2** of **Attachment C.**

In the figures below, white lines indicate fault truncations. In the fault modeling process, truncations create a linear weld between two faults and can be used for compartmentalization later when the geocellular grid is created.

Main Thrusts

Two large thrust faults run the entire length of the structure: the East Bounding and West Bounding Thrust Faults. The West Bounding Thrust Fault truncates in the east against the East Bounding Thrust Fault, as shown in **Figure 1(a)**.

Southern Faults

Three faults exist on the southern portion of the structure and are shown in **Figure 1(b):**

- The longest is MB13, shown in blue in **Figure 1(b)**, and it truncates against the East Bounding and West Bounding Thrust Faults at its base.
- Fault MB12 is shown in brick red in **Figure 1(b)**, and it truncates against the West Bounding Thrust Fault at its base.
- The Southern Crestal Fault (shown in teal in **Figure 1[b]**) truncates against the West Bounding Thrust Fault at its base and MB13 to the south.

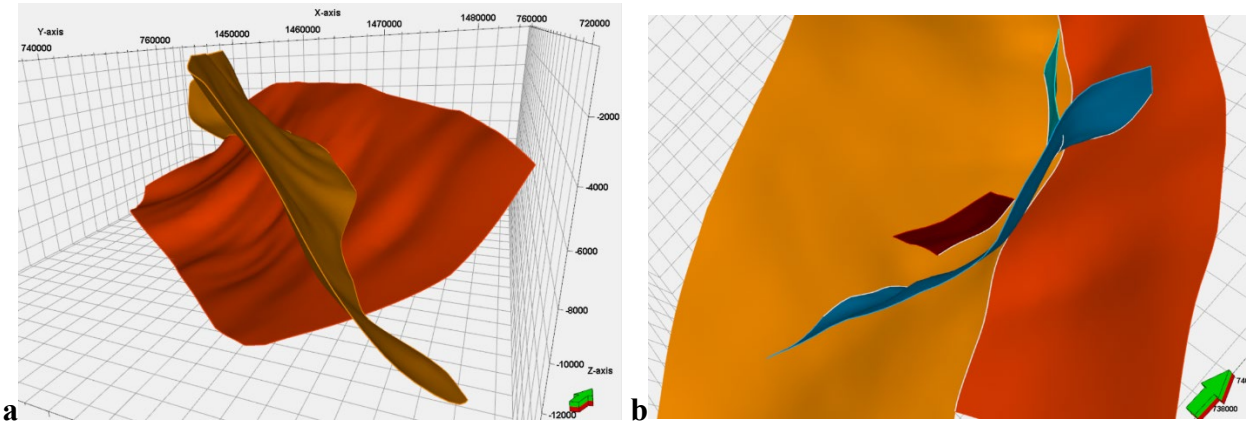

Figure 1 (a): East Bounding Thrust Fault (orange) and West Bound Thrust Fault(brown).

Figure 1 (b): MB 13 (blue), MB12 (brick red) and Southern Crestal Fault (teal) and their truncation relationships. The white lines correspond to fault truncations and the green arrow points North.

Central and Northern faults

Seven faults exist to the north of the faults in the southern section (discussed above). Six faults lie above the East Bounding and West Bounding Thrust Faults, as shown in **Figure 2.**

- The West Limb Thrust Fault (pink) is shown in **Figures 2a** and **2b**. It parallels the West Bounding Thrust Fault, truncates back against the East Bounding Thrust Fault to the east, and against the Northern Crestal Fault 2 (blue) to the northwest.
- The Central Crestal Fault 1 (violet) is truncated by the West Limb Thrust Fault at its base.
- The Central Crestal Fault 2 (dark purple) is truncated by the West Limb Thrust Fault at its base and by the Central Crestal Fault 1 to the southeast.
- The Northern Crestal Fault 1(green) is truncated by the West Limb Thrust Fault at its base and by the Northern Crestal Fault 2 to the northwest.
- The Northern Crestal Fault 2 (blue) truncates against the East Bounding Thrust Fault and the West Bounding Thrust Fault at its base.
- The Northern Crestal Fault 3 (grey) truncates against the East Bounding Thrust Fault at its base and the Northern Crestal Fault 2 to the south.
- The Downdip West Flank Cross Fault (light blue) lies completely beneath the West Bounding Thrust Fault (**Figure 2b**) and truncates against the West Bounding Thrust Fault at its top, and against the East Bounding Thrust Fault at its base.

Figure 2: 3D views of the West Limb Thrust Fault (pink), Central Crestal Fault 1(violet), the Central Crestal Fault 2 (dark purple), the Northern Crestal Fault 1(green), the Northern Crestal Fault 2 (blue), and the Northern Crestal Fault 3 (gray). The Downdip West Flank Cross Fault (light blue) is only displayed in 2b. The white lines correspond to fault truncations and the green arrow points North.

Horizon Modeling

Volume-based Modeling Theory

In the horizon modeling process, the volume-based modeling (VBM) algorithm is used to create a stratigraphic function based on the framework faults, the specified stratigraphy, and horizon interpretation. The structural model horizons are extracted as iso-values of this property, which makes the VBM approach fundamentally different from surface-based horizon modeling concepts. The stratigraphic function is defined throughout the structural model but is discontinuous across faults and unconformities. The algorithm is designed to minimize dip and thickness variations in the stratigraphic function. **Figure 3** shows an example of a stratigraphic function for a volume-based model.

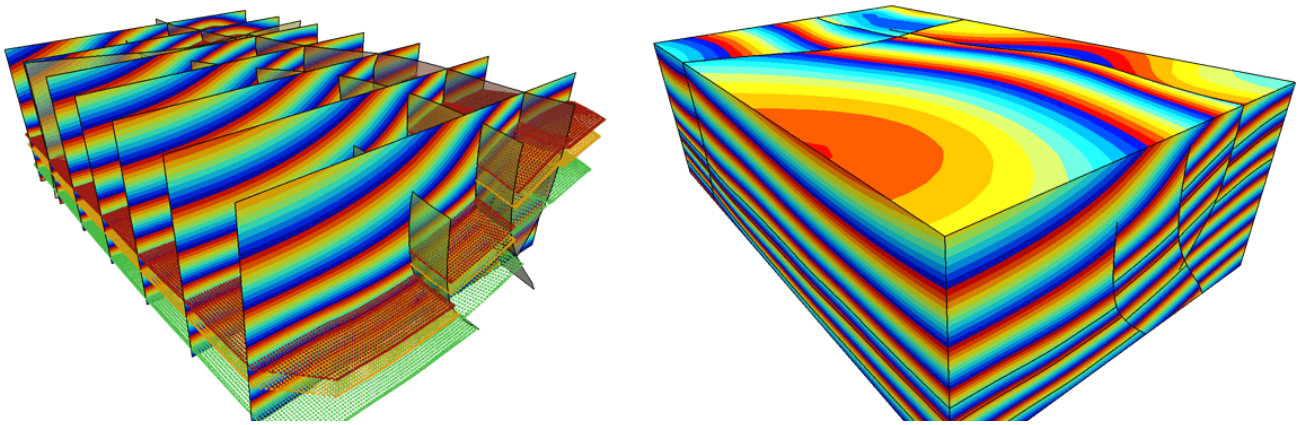

Figure 3: Stratigraphic function in sliced view with model faults and horizon interpretation (left), and in full view (right).

Modeled Horizons

Thirteen separate horizons were modeled in the North Belridge study area, listed below in **Table 1** from top to bottom. All horizons were tied to the well tops, although some well tops had to be excluded from the modeling process. The second column of **Table 1** gives the number of tops used in for each horizon in the structural framework, and the number of tops that were excluded are shown in parentheses. Other structural controls were also used to build the stratigraphic function (column 3 of **Table 1**) and were critical to modeling the structure away from the top of the anticlinal structure. The other controls included seismic interpretation for several horizons in the sequence, as well as isochore maps (maps of the true vertical thickness between consecutive horizons).

Table 1: Horizons, Wells Tops, Excluded Tops, and Other Controls

Horizon	Well Tops Used (Excluded Tops)	Other Control
MEDIA_TOP	140 (10)	Control from seismic interpretation
UPPER CARNEROS_TOP	123 (10)	
UPPER CARNEROS_BASE	121 (10)	
CARNEROS_TOP	136 (7)	Control from seismic interpretation
CARNEROS_BASE	142 (13)	Isochore map - Carneros Base to Agua Top
AGUA_TOP	143 (14)	
AGUA_BASE	137 (16)	Control from seismic interpretation
64_ZONE_U_TOP	140 (15)	Isochore map - Agua Base to U-Sand Top
64_ZONE_U_BASE	130 (15)	
64_ZONE_W_TOP	132 (15)	Control from seismic interpretation
64_ZONE_W_BASE	52 (6)	
GIBSON_TOP	29 (3)	
TUMEY	29 (1)	Control from seismic interpretation

1. A list of horizons in the structural framework is in the first column, the second column shows the number of well tops tied to the horizon in the modeling process, with the number of well tops not used in the solution is given in parentheses. The third column lists other controls (seismic interpretation, thickness grids) used to constrain the horizons in the structural framework.

The structural control inputs and the fault framework were used in the VBM process to create the final structure.

When the VBM process runs, it uses the tops and other inputs from all horizons together in a 3D space to solve for the stratigraphic function (shown in **Figure 3**) simultaneously. The solution for each horizon is then inspected and refined. During the quality control process for the structural framework, some of the well tops were excluded from the solution; typically, this was because the excluded top was very close to another top with a different elevation and caused unrealistic short-wavelength anomalies in the horizon, or due to poor log quality resulting in insufficient definition to reliably make a pick. Some tops that gave anomalous zone thicknesses were also excluded. The number of excluded tops for each horizon are given in **Table 1** in parentheses. **Figure 4** shows the horizon for the 64 Zone W Sandstone top, with the well tops for that horizon displayed as spheres. The well tops in green were used in the solution while the tops posted in red were excluded.

After many quality control iterations, the horizon and fault geometries converged on a geologically sound solution for the structure, as shown in **Figure 4.**

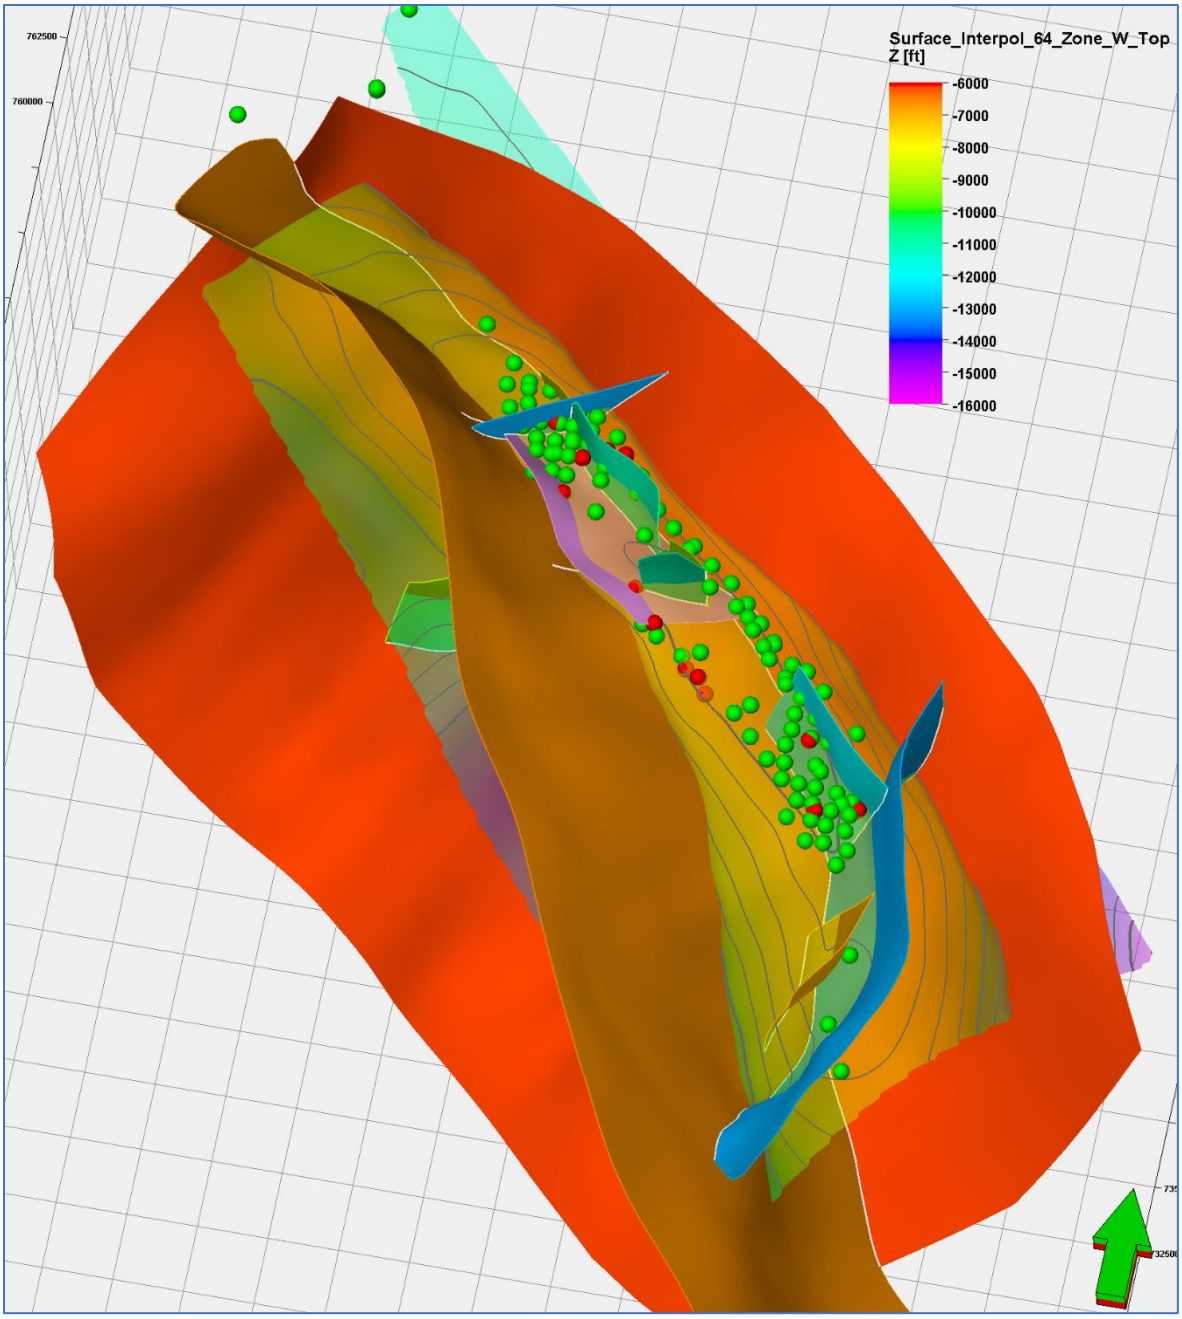

Figure 4: 64 Zone W Sandstone top horizon, shown with faults and well tops (posted as spheres). The well tops in green are the tops which were tied to the surface in structural modeling, and the tops shown in red were excluded during VBM. The green arrow points north.

Building Geocellular Grids from the Structural Framework

Pillar Geocellular Grid Theory

Pillar gridding is the process of using faults in the fault model as a basis for generating a 3D geocellular grid. In this type of gridding, faults retain their shape from the structural framework, and the corner-point grid pillars take on the dip of a nearby fault, as cells in a geocellular model must reside on one side of the fault or another. This gridding process results in a set of pillars along and between faults. The grid has no layers, only a set of pillars with user-supplied X and Y increments between them (like a pin cushion), and layering is introduced to the grid when making horizons and zones.

Creation of the Pillar Geocellular Grid

Creation of the pillar geocellular grid begins with creating a two-dimensional grid (skeleton) between the mid points of the key grid pillars. Then, top and bottom grids are generated from the top and bottom points of the key grid pillars, as shown in **Figure 5**.

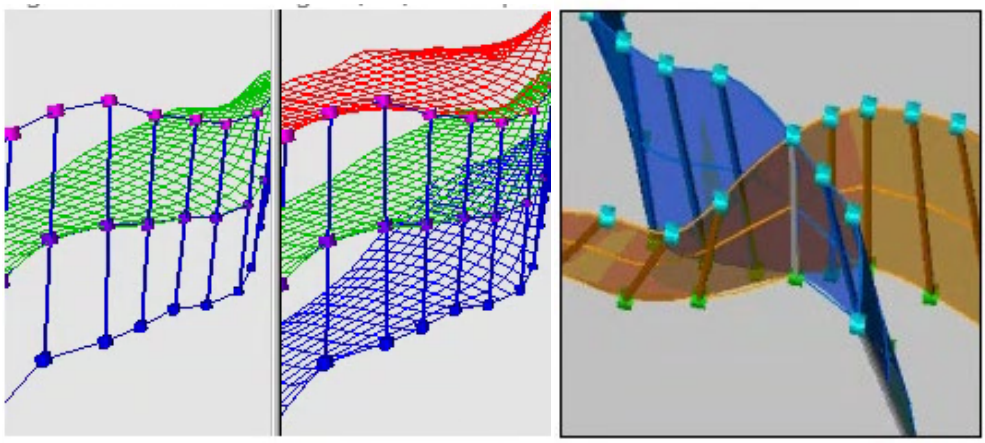

Figure 5: Mid-skeleton grid (left) and top-, mid-, and base-skeleton grid (middle) defined between shape points. Faulting from the fault model also provides additional detail to the skeleton grid through pillars that represent the plane of faulting (right).

The Z coordinates of the top, middle, and bottom grids have nothing to do with the positions of any future horizons, and, therefore, allow for grid pillars to be restructured based on key datapoints of faults in the structural model.

The pillar geocellular grid is ultimately restricted to the domain of the skeleton model in space once faults and layers are assigned. The vertical limits were from the Media Shale horizon to the Tumey horizon (**Table 1**), and the horizontal limits were defined by a polygon (**Figure 6)** that encompassed the locations of the well with porosity logs. The other critical parameters are cell dimensions in X, Y and Z. The horizontal dimensions for each cell are approximately 150 by 150 feet. The layering for the geocellular model uses the proportional method (i.e., a fixed number of layers per zone), so the cell height varies proportionally with the thickness of the zone. For the 64

Zone W Sandstone, there are 26 layers, and the average cell height is approximately 13 feet. For the 64 Zone U Sandstone, 7 layers were used, and for the shales above, below, and between the 64 Zone U and W Sandstones, 2 layers were used. **Figure 6** shows the cell height property for the 64 Zone W Sandstone and the vertical extents of the model. The faults are displayed for reference, and the 150-by-150-foot cell dimension and grid orientation can be inferred from the square cells in the cell height property.

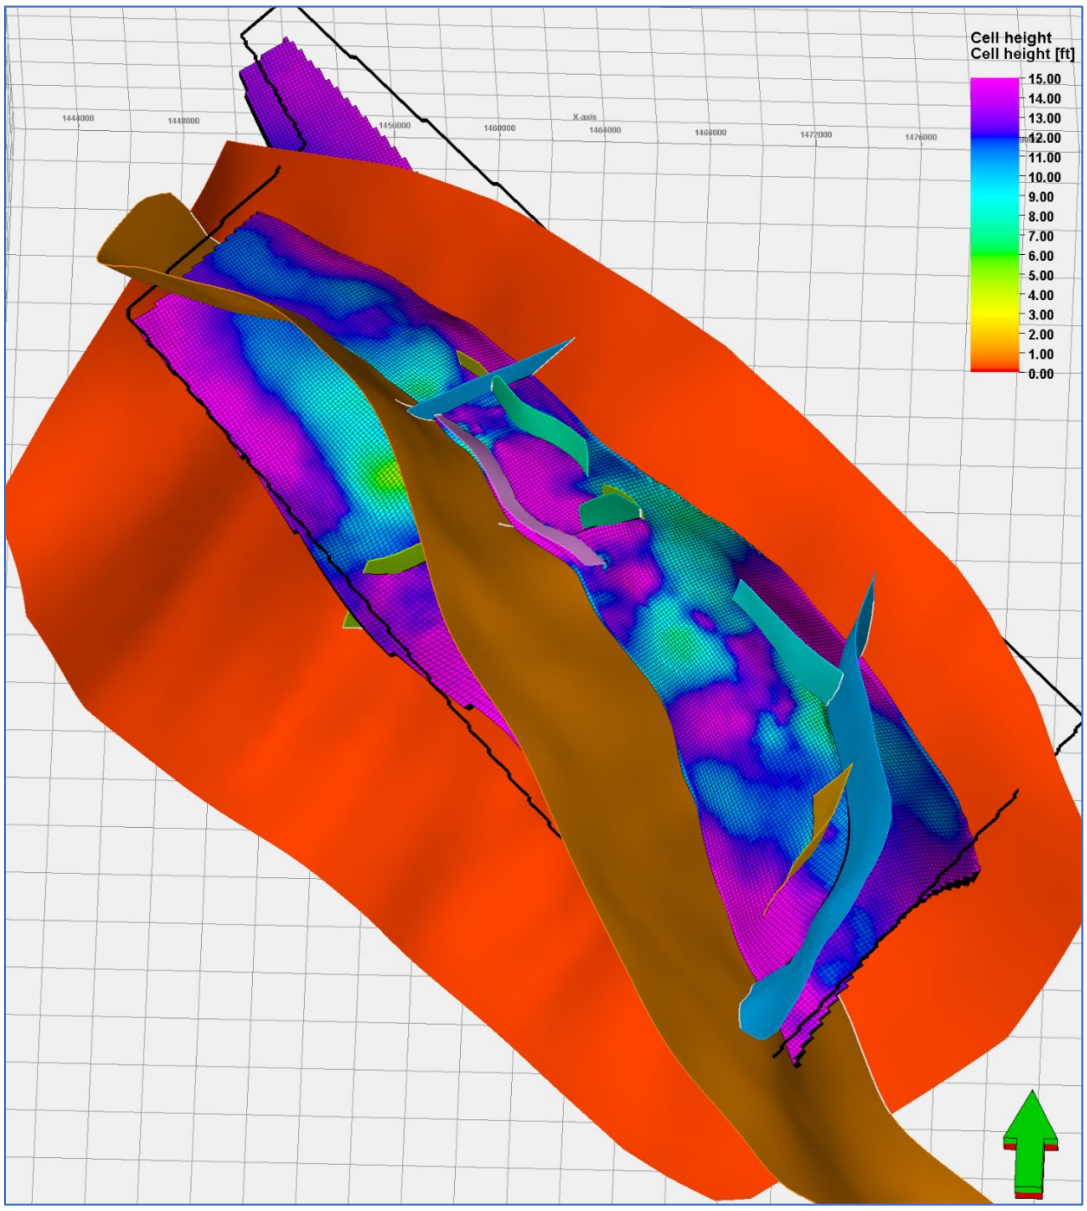

Figure 6: The cell height property for the 64 Zone W Sandstone is displayed along with the faults from the structural framework and the polygon used to set the limits for the pillar geocellular grid. The green arrow points north.

Petrophysical Property Distribution in the Geocellular Grid

Porosity

As described in **Section 3.3.1** of **Attachment C**, a density-neutron crossplot porosity was computed as an estimate of total porosity that accounts for the effects of mineralogy and fluid saturation on log measurements. In discussions with the petrophysical team, 24 porosity units (pu) was set as the reasonable upper limit for the petrophysically derived total porosity (PHIT). As a preconditioning step, the PHIT logs were passed through a process that set any values greater than 24 pu to undefined.

At this point, the PHIT well logs were upscaled to the grid cells in the geocellular model. A simple arithmetic average was determined to be the most accurate method for upscaling the well logs into the coincident cells in the geocellular model. A zone mapping technique was also employed to assure that the well logs are accurately mapped into the correct cells for those wells where the well top was excluded from the structural framework (the well tops displayed in red in **Figure 4**). This technique finds the exact location of the intersection of horizon with the wellbore at the top and base of each zone and corrects for the distance to the picked well tops.

After the well logs have been mapped into their corresponding cells in the geocellular model, they are used as inputs to the petrophysical modeling process. Petrophysical modeling uses the upscaled cells and a variogram to distribute the porosities into each cell in the model with a stochastic simulation technique called **Gaussian Random Function Simulation**. The variogram parameters for the distributions for the five zones are given in **Table 2**.

Table 2: Variogram Parameters for the PHIT Distribution in the Geocellular Model

Using the variogram and upscaled cells, the PHIT property is distributed throughout the model. The final property for the 64 Zone W Sandstone is shown in **Figure 7**.

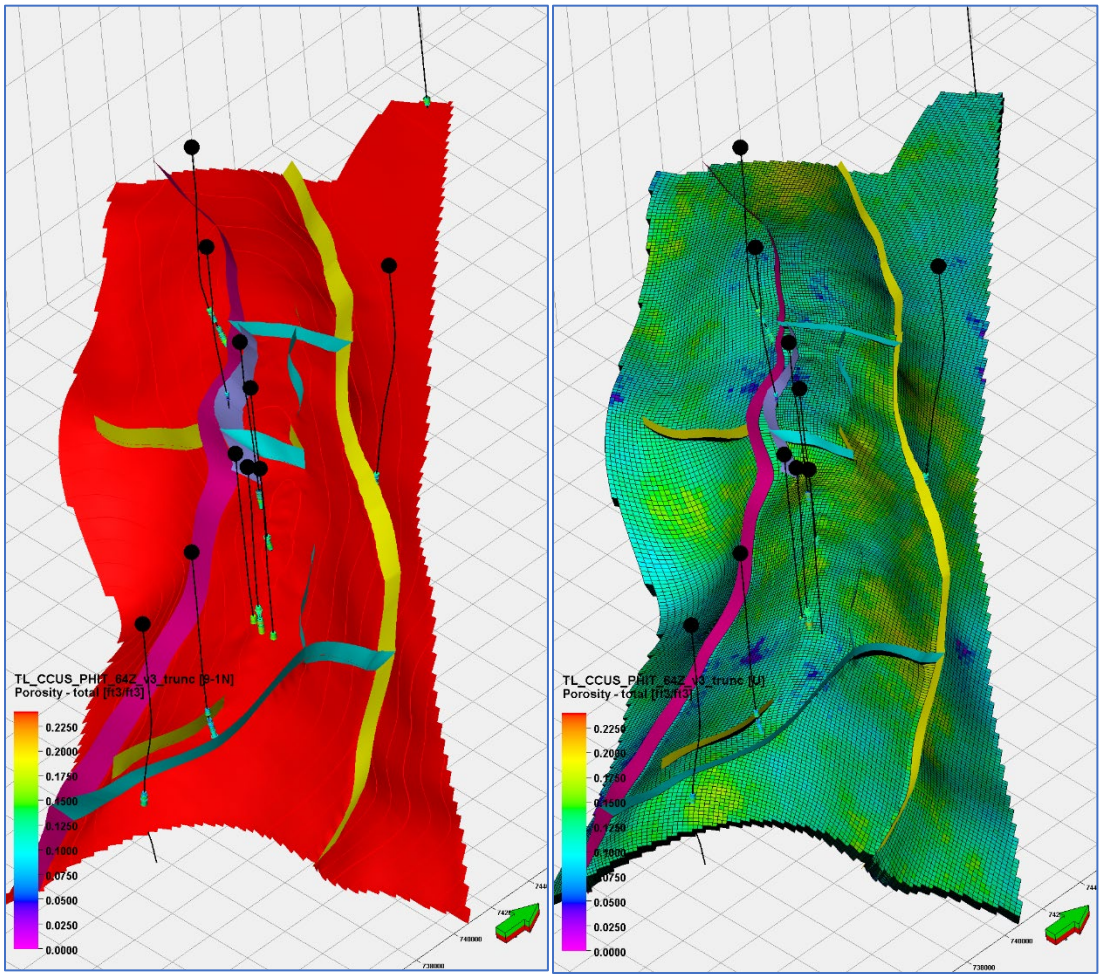

Figure 7: On the left are the PHIT well logs, pillar faults, and base of the 64 Zone W Sandstone. On the right is the distributed porosity property for 64 Zone W Sandstone. The green arrow points north.

Distributions of original porosity logs, upscaled logs, and modeled porosity are generally concordant. The modeled porosity distribution has an insignificant bias toward lower porosity values (a shift of approximately 1 pu from original and upscaled well logs), which can be attributable to interpolation and extrapolation of the input log data. **Figure 8 (a–d)** shows

correlations within the Lower Santos Shale, U-Sandstone, U-Shale, and W-Sandstone. The upscaled well log porosity within the shale intervals appears to have spikes, which can be attributed to the lack of samples being represented within the model layers. The shale intervals only have two layers each and 11 wells, equal to 22 total samples represented in the histograms. In comparison, the U and W Sandstones have over 5 layers each in the geocellular model, resulting in a smoother distribution of upscaled samples.

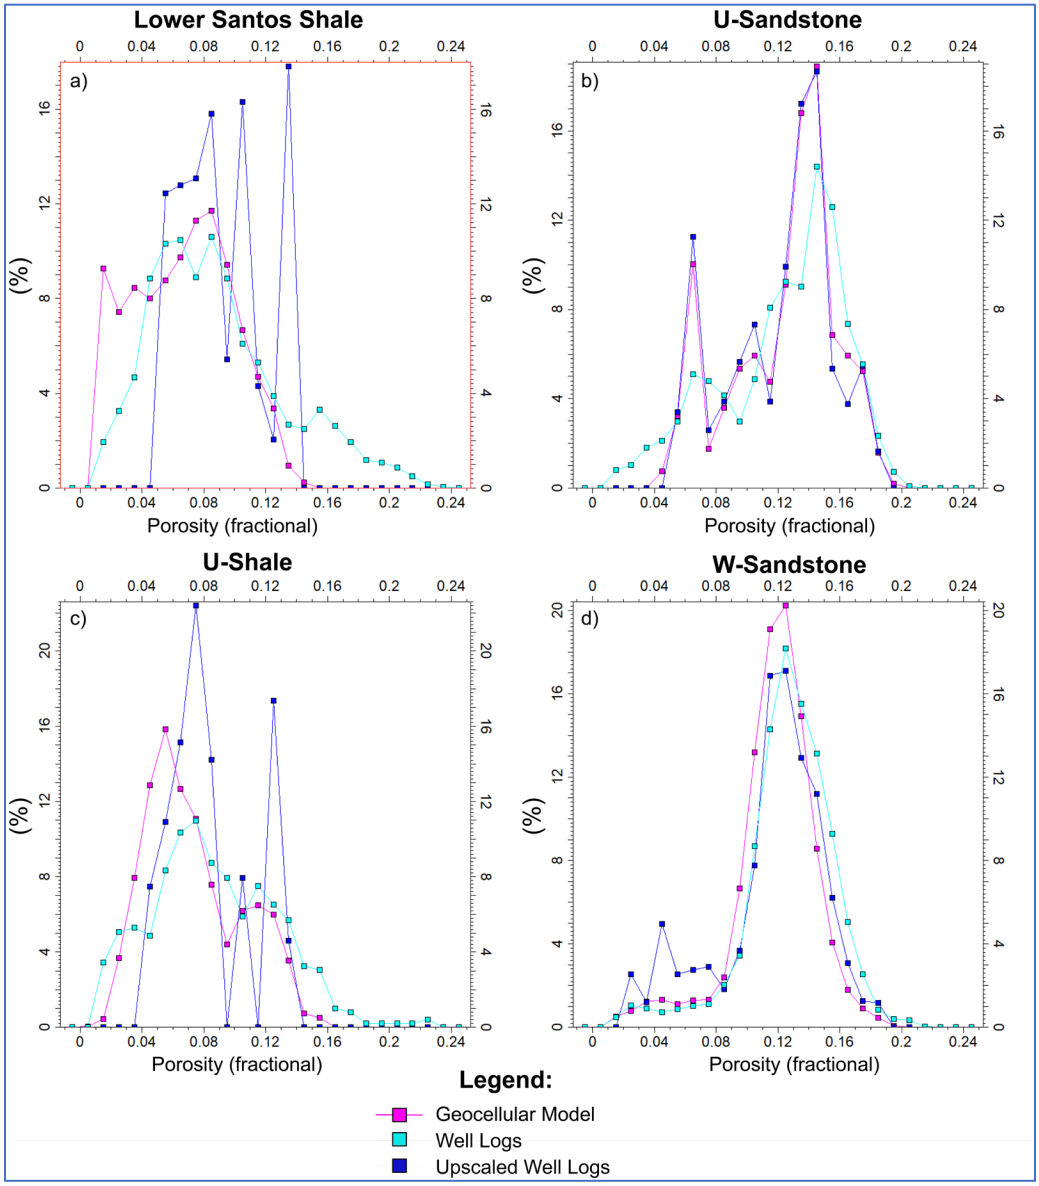

Figure 8: Histograms showing porosity distributions in the 64 Zone. The three lines represent well log inputs, upscales logs, and geocellular value distributions within the 3D model domain.

From upper left to bottom right: a) Lower Santos Shale, b) U-Sandstone, c) U-Shale, d) W-Sandstone.

Permeability

Air permeability was calculated for all zones using constant values, algorithms based on other properties in the model, and collocated co-kriging using regional information and PHIT distributions as shown in **Table 3**.

Table 3: Permeability Equations by Zone

Zone	K_{air} equation
MEDIA_TOP-UPPER CARNEROS_TOP	K_{air} = 0.0001

2. Constants and statistics are in millidarcies.

For the shale-prone zones above, below, and between the 64 Zone U Sandstone and W Sandstone, permeabilities were set to a constant value based on regional data. An algorithm was developed to predict unstressed air permeability in the 64 Zone Sandstones using wireline logs as inputs: computed total porosity and normalized gamma ray for the U-Sandstone, and total porosity and distance from top of the sandstone unit for the W-Sandstone. The prediction algorithm trained with available conventional core data and was used to generate permeability estimates for all the wells with valid porosity log data. Cross plots comparing actual vs. predicted Log of Permeability to air for the training and test sets of the predictive model are presented in **Figure 9**. The U-Sandstone and W-Sandstone intervals were calculated using the algorithm mentioned above, and equations shown in **Table 3**, using the Petrel™ calculator on the existing 3D grid. Interpolated permeability values (W Sandstone) with associated distribution cross plots related to the Kair equation are shown in **Figure 10**. The sand-prone intervals outside of the 64 Zone relied on statistical analysis of well/core data (mean and stand deviations in Table 3) and collocated co-kriging of PHIT using a constant coefficient of 0.8 at each cell location. Each of these sand-prone intervals were given output ranges bounded between either 0.001mD – 1,000mD or 0.1 mD – 1,000 mD. Gaussian

random function simulation interpolation of the Upper Carneros Sandstone, Lower Carneros Sandstone, Agua Sandstone, and Gibson Sandstone used parameters in **Table 4**.

1. Model properties are **bold**.
2. Constants and statistics are in millidarcies.

Distributions of permeabilities within the gridded model can be compared against statistically derived data from core measurements, as this data set was used for calibrating well log estimates and to derive inputs for collocated co-kriging. **Table 5** shows comparisons of statistics (mean and standard deviation) from core data and from the 3D geocellular model. All zones have mean permeabilities within 1 mD when comparing core and modeled data, except for the W Sandstone (~38 mD). The median values, which are a more representative comparison for log-scale measurements, of W Sandstone core and modeled permeability are within ~20 mD (28.5 mD and 8.9 mD, respectively). **Figure 11** shows porosity and permeability core data relative to porosity and permeability from the geocellular model. Overall, there is a strong correlation in input and modeled data.

Table 5: Comparison of Input Core data to gridded permeability in the Geocellular Model

	Core Derived Statistics - Inputs		Geocellular Model Statistics	
Zone	Mean (mD)	Standard Deviation (mD)	Mean (mD)	Standard Deviation (mD)
UPPER CARNEROS_ TOP-UPPER CARNEROS_BASE	0.01879	0.03314	0.0192	0.0314
CARNEROS_TOP-CARNEROS_BASE	0.01879	0.03314	0.0199	0.0382
AGUA_TOP-AGUA_BASE	2.587	3.958	2.688	3.778
64_ZONE_U_TOP-64_ZONE_U_BASE	1.123	1.362	0.971	1.052
64_ZONE_W_TOP-64_ZONE_W_BASE	55.967	1.094	17.472	26.001
GIBSON_TOP- TUMEY	2.587	3.958	2.264	2.769

1. Limited core samples from the Upper Carneros Sandstone, Carneros Sandstone, Agua Sandstone, and Gibson Sandstone resulted in groupings of input statistics based on regional understanding and professional judgement.
2. mD = millidarcies

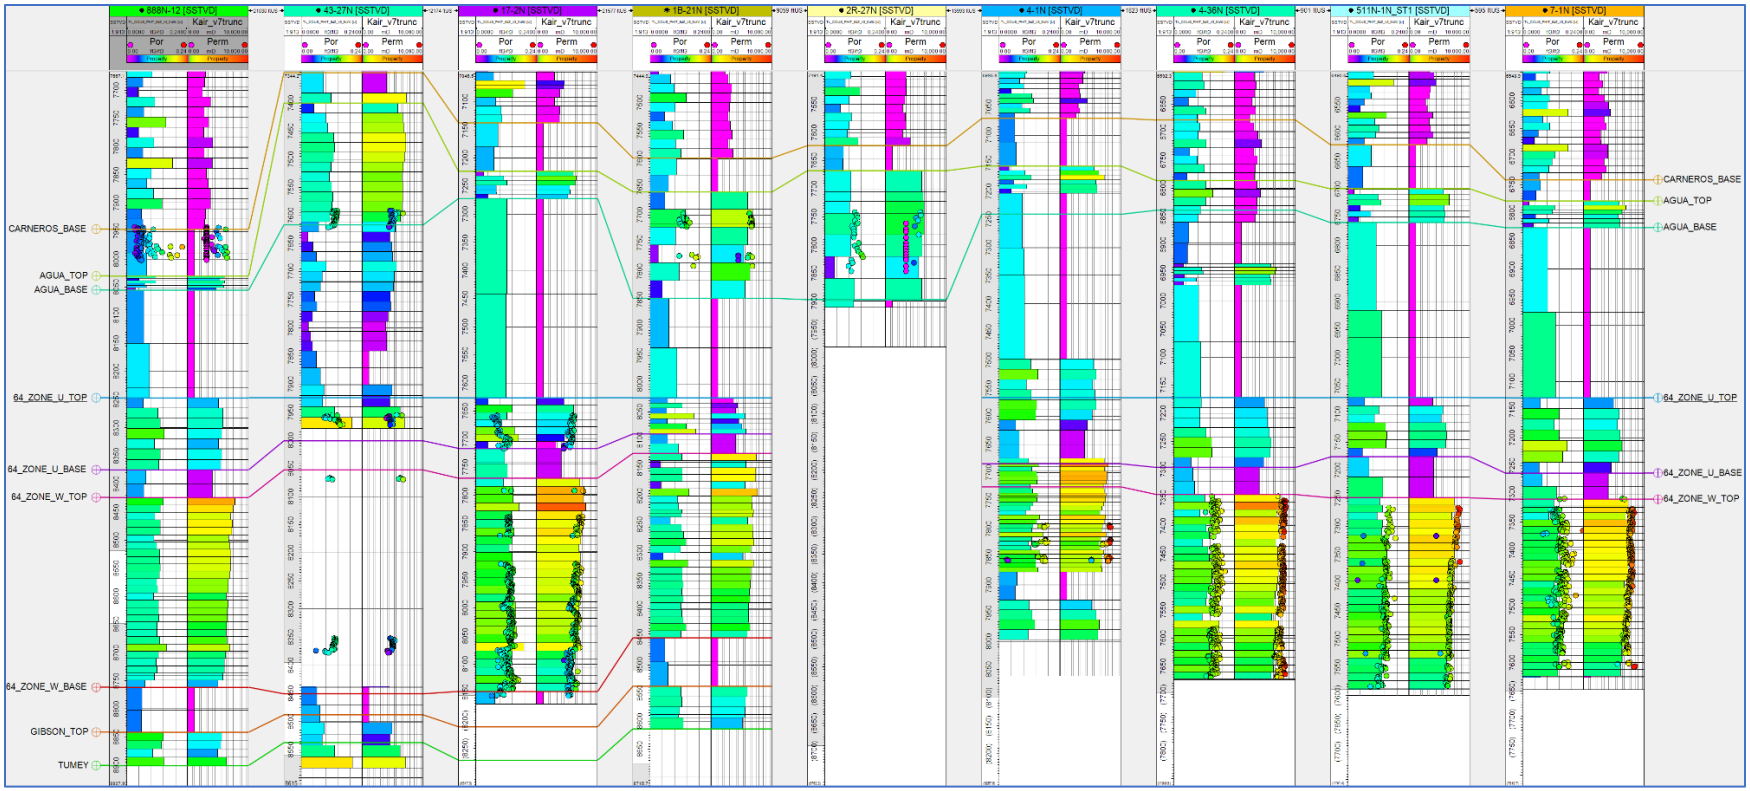

Figure 11: Porosity and permeability core data plotted with gridded porosity and permeability values along the borehole trajectory from the geocellular model. Porosity is in the left track with core data plotted as circles with color fill and gridded property as color fill line. Scale on the porosity track is 0-24% (fractional). Permeability is in the right track with core data plotted as circles with color fill and gridded property as color fill line. Scale for the permeability track is log scale from 0.00001 – 10,000 millidarcies. Well 43-27N penetrates the modeled West Limb thrust fault where the W Sandstone is faulted out.

3D Data Processing History and Flow

History

From 2012 through 2016 Aera undertook a reprocessing effort of the greater Belridge producing complex and surrounding areas. This included the South Belridge and Antelope Hills/NS40 surveys, as well as other surveys in the vicinity of the North Belridge and South Belridge fields. The initial processing (2012-2015) focused on the South Belridge survey but also involved several other surveys, located south and west of South Belridge. These were subsequently merged into a large data volume called the ABCSB dataset (or merged survey).

The data processing was conducted, in parts, by Excel Geophysical, WesternGeco and Shell Onshore Imaging Americas. In 2016, the Antelope Hills/NS40 survey was merged with the prior merged volume from ABCSB. Finally, in 2017, the processing products from these cumulative

efforts were extracted over the North Belridge field area and shipped to Advanced Geophysical Technology (AGT) for new velocity analysis, modeling and a Pre-Stack Depth Migration delivered to Aera in 2018. The processing flows for all three of these processing stages are described, in detail, below.

Phase 1: 2012-2015 Processing (Merge survey resulting in ABCSB)

Front-end processing (geometry, first-break picking, initial statics corrections, etc.) was conducted by WesternGeco.

WesternGeco front-end work: The processing was started from field shot-gathers. This included elevation and refraction statics solutions, appending geometry to trace headers, QC of geometry and edits of shot locations (if necessary), and picking first breaks. The products from these processing efforts were then delivered to Shell as input to the remaining processing flow, described below.

Processing Flow

REFRACTION STATICS: Each survey had contractor (as previously discussed, above) provided first breaks and refraction statics in the headers. The refraction statics were computed using the respective vendor methods. After Qcing the quality of the first breaks, it was decided to repick and rederive refraction statics using the Geotomo TomoPlus software. Each survey is a mix of dynamite and vibroseis sourced records. For better and consistent first break picking, all surveys were time and phase matched prior to picking. The survey match parameters were determined from analysis of the elevation stacks. See paragraph Survey Match for detail.

Near surface refraction statics were determined using the Geotomo TomoPlus software using shots and receivers from all six surveys. A multi-pass iterative approach was used. Pass one used a 3-layer initial model based on the first-break picks and a smoothing control of 10. Pass two used the output from pass one as input with a smoothing control of 1.0. The final pass used the output from the second pass as the input and a smoothing control of 0.1. 24 | P a g e Aera Merge 2014 Processing Report Confidential Statics were solved using a datum of 4000ft, and a replacement velocity of 6000 ft/s. We used only offsets from 2000 ft to 10 000 ft where the first break picks were most accurate.

NOISE ATTENUATION: Denoising was run in both shot and receiver domains and in cross-spread domains with the objective of first removing linear ground roll noise followed by the high amplitude noise that would affect the calculation of the Deconvolution operator. Stationary noise was removed using the BUZOFF (Shell internal code) operation prior to removing linear ground roll noise.

The noises observed on these data included:

- Ground roll: strong and (extremely) low velocity, as low as 500 ft/s – 600 ft/s
- Air wave: strong, especially for the vibroseis data
- Production noise due to the oil field: strong, dispersive and generally not coherent
- Unknown source coherent noise: possible related to surface facilities.

The ground roll energy in the middle of the oil field was the most challenging. Therefore, several steps were applied to attack ground roll and random/coherent noise. For linear ground roll noise attenuation, TREX (Shell internal code) was used to model the dipping low frequency ground roll linear noise. To attenuate the remaining noise, DIVERS (Shell internal code) was run on frequency sub-bands in the shot and receiver domains to attenuate high amplitude noise bursts in the data. Prior to attenuating the noise bursts, a pass of surface consistent gain was run for both shot and receiver components The most challenging noise in this area is the noise generated by the operational oil field in the southern portions of the South Belridge survey. On some receivers, this noise so dominated that no signal was observed, and these receivers were dropped from processing.

SCALING: Surface consistent scaling was performed to balance amplitudes before the DIVERS (Shell Internal Code) operation. Shot and receiver scalars were computed for each survey individually.

SURVEY MERGING: Elevation stacks for each survey were created to conduct the survey wavelet matching. For consistency, shot and receiver elevation statics were calculated using a datum of 4000 ft and replacement velocity of 6000ft/s. We encountered significant challenges to find signal for matching in some of the overlap zone. Of the six surveys in total to merge, South Belridge, Apex, Cymric, and Belgian surveys are a mix of dynamite and vibroseis, Prior to the survey matching, each survey had a vibroseis to dynamite filter applied. Each survey was stacked separately using the same velocity, the same datum correction, and binned to the merge grid which is iline55x crossline55. South Belridge was rebinned from il55 x xl82.5 to il55 x xl55

DECONVOLUTION: Surface consistent deconvolution was run using the global option in the Techco Deconvolution package (Techco Geophysical Services software). This option calculates the line, shot, and receiver components, but only the shot and receiver components are applied. By applying only the shot and receiver components, the amplitude spectra variations between the shots and receivers is corrected (residual deconvolution), and the average wavelet remains in the data. Prior to deconvolution, a spherical divergence correction with an alpha of 1.5 was applied along with a deabsorption correction with an alpha of 0.2. The near offsets have minimal coherent energy, so for the deconvolution operator design, an internal mute was applied. This allows the deconvolution operator to be designed more on signal, and to be less influenced by the noise in the data.

Techo Deconvolution Parameters

- Operator: 120ms
- PreWhitening: 0.1
- Mode: Global
- Window

Offset (ft)	Top Window (ms)	Bottom Window (ms)
1600	1500	3000
10000	2500	450

VELOCITIES: The Techco Velanal software package (Techco Geophysical Services) was used to perform one pass of stacking velocity analysis. Constant velocity scans were performed and picked every 60x60 bins. After obtaining an initial velocity function, a second velocity analysis was performed using percentages from 80% to 120% with 2% increment. As the data quality in the west was poor, the following data preconditioning was applied prior to making velocity scans: - Harsh 4D denoise (Madcow) (Shell proprietary noise reduction) - AGC with short (500 ms) window - Frequency high cut: 3-8-25-30 Hz

REFLECTION STATICS: One pass of surface consistent reflection statics was calculated after merge and deconvolution using the Jaguar operation (Shell internal code). The best results were obtained by using reference stacks with 4D MADCOW denoise applied post-stack. However, unsolved statics remain in the west side of the merged dataset. The number of residual statics passes was limited to one due to minimal improvement after the first pass.

Parameters
Window: 1000-3000ms
Freq: 3/8 - 25/30Hz
Maximum allowable shift: +/- 60m

Phase 2: 2016 Processing (Antelope Hills/NS40; subsequently merged with ABCSB)
Front-end processing (geometry, first-break picking, initial statics corrections, etc.) was conducted by Excel Geophysical (Antelope Hills/NS40).

Excel Geophysical front-end work: The processing was started from field shot-gathers. Front-end processing included elevation and refraction statics solutions, appending geometry to trace headers, QC of geometry and edits of shot locations (if necessary), and picking first breaks. The products from these processing efforts were then delivered to Shell as input to the remaining processing flow, described below.

Processing Flow for Antelope Hills/NS40 ONLY

- Reformat Geometry QC and correction (where needed)
- Survey match before tomography (South Belridge portion of ABCSB + NS40/Antelope Hills)
- First break picking for NS40 only, used ABCSB first break picks obtained on 2012-2015 project
- Tomographic refraction statics for merged NS40 (Antelope Hills) + ABCSB (South Belridge)… [Replacement velocity: 6000ft/s, datum: 4000 ft]
- Spherical divergence correction

- Extrapolation of the ABCSB (South Belridge portion) stacking velocity over the NS40 survey
- Linear ground roll noise attenuation in shot & receiver domains
- Random/coherent noise attenuation in shot & receiver domains
- Trace to trace scaling
- Deabsorption
- Surface consistent deconvolution
- Noise attenuation after deconvolution
- Surface consistent residual reflection statics
- Velocity analysis
- Survey wavelet match (South Belridge portion of ABCSB + Antelope Hills/NS40)
- Variable slotted data preparation
- Data regularization and infill Migration data preparation

-----> Output to AGT for Velocity Analysis, Modeling and Pre-Stack Depth Migration (see below)

Phase 3: 2017/2018 Processing (New Migration of North Belridge area)

3-D Land Seismic Processing Flow Advanced Geophysical Technology Kirchhoff PSDM(VTI/TTI)	
Processing Steps	Actions/ Results
Input data and QC (From Shell Onshore Imaging Americas)	
Load and QC Input Velocity Model	• Compare velocity cube to survey geometry to ensure compatibility • QC input data
Stack 3D Data Volume	• Compare velocity cube to survey geometry to ensure compatibility • QC input data
Data Preconditioning	• Interpolation • Noise Attenuations etc.
Velocity Model Building (Isotropic Portion)	
Initial Testing of Input Data	• Check geometry, input data, Initial velocity model

Kirchhoff Migration Parameter Testing	• Various tests for computing needed migration aperture • Determine variable grid • Test for amplitude compliancy
Velocity Model Building – 3D	• 4 iterations of isotropic tomographic velocity updating to converge on final standard Isotropic depth velocity field
Iteration 1: Global Update of Sediment Velocities	• Input Kirchhoff gathers • 3D Tomography- Global velocity update- Iteration 1 • QC Stack and Gathers-analyze for flatness-inversion • QC Residual move-out picking
Iteration 2: Global Update of Sediment Velocities	• QC Stack and Gathers-analyze for flatness/inversion • QC Residual move-out picking
Repeat as Above Until Isotropic Velocity Convergence	• Up to 4 Iterations
Velocity Model Building (VTI/TTI) (Anisotropic Portion)	
Anisotropy – Iteration 1 Check for epsilon & delta	• Incorporate wells into data volume • Determine anisotropy data parameters • Update velocity model with anisotropy
Anisotropy Velocity Model – Q.C. and Iterate as necessary - finalize	• Check Well ties • Q.C. Epsilon, Delta Velocity Cubes • Update and iterate Anisotropy as needed. • Finalize Velocity Field
Final Velocity Model and Migration - Kirchhoff	
Final Raw (VTI/TTI) Kirchhoff Migration Stack and Gathers	• Gathers- AVO Compliant
Post-Migration Gather processing RNMO as necessary.	• RNMO applied to flatten gathers • Test for AVO compliancy (Fidelity of gathers- Frequency and Amplitude)
Post Migration Processing	• Filtering • Final Mute • Amplitude balancing • Azimuthal filter

Abstract: Cyclic peptides and depsipeptides are a diverse class of natural products with a wide range of biological activities. Herein, we report the synthesis of cyclic peptides and depsipeptides by intramolecular thiol-ene reaction. Linear peptide precursors containing cysteine and dehydroalanine residues undergo cyclization in the presence of a photocatalyst and visible light irradiation. The reaction is compatible with a variety of amino acid side chains and can be used to synthesize cyclic peptides containing 5−21 amino acid residues. Cyclic depsipeptides can be synthesized by the thiol-ene reaction of linear peptide precursors containing a thiol-substituted α-hydroxy acid residue. The thiol-ene reaction can be used to synthesize cyclic peptides containing a thioether linkage between the side chains of two cysteine residues.

Introduction

Cyclic peptides and depsipeptides are a diverse class of natural products with a wide range of biological activities.[1] Many cyclic peptides and depsipeptides have been developed as therapeutic agents, including the immunosuppressant cyclosporin A, the antibiotic vancomycin, and the anticancer agent romidepsin.[2] The cyclic structure of these peptides can confer resistance to proteolytic degradation and can constrain the peptide into a bioactive conformation.[3] Cyclic peptides and depsipeptides are typically synthesized by the cyclization of linear peptide precursors. Macrocyclization can be challenging because it competes with intermolecular oligomerization and polymerization reactions.[4] Many methods have been developed for the synthesis of cyclic peptides and depsipeptides, including amide bond formation, ester bond formation, and transition metal-catalyzed cross-coupling reactions.[5]

The thiol-ene reaction is the addition of a thiol to an alkene to form a thioether.[6] The reaction can be initiated by radicals, bases, or nucleophiles. Radical-initiated thiol-ene reactions have been used in polymer chemistry, materials science, and bioconjugation.[7] The reaction is typically anti-Markovnikov selective and proceeds with high efficiency under mild conditions. Intramolecular thiol-ene reactions have been used to synthesize macrocycles, including cyclic peptides.[8] However, the application of the thiol-ene reaction to the synthesis of cyclic peptides has been limited by the availability of suitable linear precursors.

Herein, we report the synthesis of cyclic peptides and depsipeptides by intramolecular thiol-ene reaction. Linear peptide precursors containing cysteine and dehydroalanine residues undergo cyclization in the presence of a photocatalyst and visible light irradiation. The reaction is compatible with a variety of amino acid side chains and can be used to synthesize cyclic peptides containing 5−21 amino acid residues. Cyclic depsipeptides can be synthesized by the thiol-ene reaction of linear peptide precursors containing a thiol-substituted α-hydroxy acid residue. The thiol-ene reaction can be used to synthesize cyclic peptides containing a thioether linkage between the side chains of two cysteine residues.

Results and Discussion

We began our investigation by synthesizing linear peptide precursor **1** containing cysteine and dehydroalanine residues. Peptide **1** was synthesized by solid-phase peptide synthesis using Fmoc-protected amino acids. The dehydroalanine residue was introduced by the elimination of a phosphoserine residue. Peptide **1** was cleaved from the resin and purified by reverse-phase HPLC.

Scheme 1. Synthesis of Linear Peptide Precursor **1**

Peptide **1** was dissolved in DMF and irradiated with visible light in the presence of a photocatalyst. We screened several photocatalysts and found that fac-Ir(ppy)$_3$ was the most effective. The reaction proceeded to completion in 2 h and afforded cyclic peptide **2** in 85% yield. The structure of **2** was confirmed by ^{1}H NMR, ^{13}C NMR, and high-resolution mass spectrometry.

Table 1. Optimization of the Thiol-Ene Cyclization of Peptide **1**

entry	photocatalyst	solvent	time (h)	yield (%)
1	fac-Ir(ppy)$_3$	DMF	2	85
2	Ru(bpy)$_3$Cl$_2$	DMF	2	72
3	Eosin Y	DMF	2	41
4	fac-Ir(ppy)$_3$	MeCN	2	78
5	fac-Ir(ppy)$_3$	DMF	1	81
6	none	DMF	2	0

We next investigated the scope of the reaction with respect to the amino acid side chains. We synthesized a series of linear peptide precursors containing different amino acid residues and subjected them to the optimized reaction conditions. The reaction was compatible with a variety of amino acid side chains, including aromatic, aliphatic, polar, and charged residues. The reaction was also compatible with peptides containing multiple cysteine and dehydroalanine residues.

Figure 1. Scope of the thiol-ene cyclization. (a) Peptide **3**. (b) Peptide **4**. (c) Peptide **5**. (d) Peptide **6**.

We then investigated the synthesis of cyclic depsipeptides by the thiol-ene reaction of linear peptide precursors containing a thiol-substituted α-hydroxy acid residue. Peptide **7** was synthesized by solid-phase peptide synthesis using Fmoc-protected amino acids and a thiol-substituted α-hydroxy acid building block. Peptide **7** was cleaved from the resin and purified by reverse-phase HPLC. Peptide **7** was dissolved in DMF and irradiated with visible light in the presence of fac-Ir(ppy)$_3$. The reaction proceeded to completion in 2 h and afforded cyclic depsipeptide **8** in 78% yield.

Scheme 2. Synthesis of Cyclic Depsipeptide **8**

We also investigated the synthesis of cyclic peptides containing a thioether linkage between the side chains of two cysteine residues. Peptide **9** was synthesized by solid-phase peptide synthesis using Fmoc-protected amino acids. Peptide **9** was cleaved from the resin and purified by reverse-phase HPLC. Peptide **9** was dissolved in DMF and irradiated with visible light in the presence of fac-Ir(ppy)$_3$. The reaction proceeded to completion in 2 h and afforded cyclic peptide **10** in 82% yield.

Scheme 3. Synthesis of Cyclic Peptide **10**

Conclusion

In conclusion, we have developed a method for the synthesis of cyclic peptides and depsipeptides by intramolecular thiol-ene reaction. Linear peptide precursors containing cysteine and dehydroalanine residues undergo cyclization in the presence of a photocatalyst and visible light irradiation. The reaction is compatible with a variety of amino acid side chains and can be used to synthesize cyclic peptides containing 5−21 amino acid residues. Cyclic depsipeptides can be synthesized by the thiol-ene reaction of linear peptide precursors containing a thiol-substituted α-hydroxy acid residue. The thiol-ene reaction can be used to synthesize cyclic peptides containing a thioether linkage between the side chains of two cysteine residues.

DUAL SPACED NEUTRON SHOP CALIBRATION

Tool Name: DSNT - 11660717 **Reference Calibration Date:** 31-Jul-19 13:41:52

Engineer: T. FOSTER **Calibration Date:** 16-Nov-19 14:57:20

Software Version: WL INSITE R6.2.1 (Build 2) **Calibration Version:** 1

Logging Source S/N: 61807B

Tank Serial Number: 105014

Reference value assigned to Tank: 54.500

Snow Block S/N: TRUCK 21

Calibration Tank Water Temperature: 76 degF

Min. Tool Housing Outside Diameter: 3.625 in

CALIBRATION CONSTANTS			
Measurement	Prev. Value	New Value	Control Limit On New Value
Gain:	0.97427	0.97268	0.900 - 1.100

WATER TANK SUMMARY (Horizontal Water Tank)

WELL: 4-1
FIELD: North Belridge

PROCEDURE SUMMARY

1. Conventional cores #3-#5 were received refrigerated at approximately 40 F.

2. Cores were oriented and slabbed in 1/3 - 2/3 portions. The 1/3 geologic portions were photographed under white and ultraviolet light, 12' per photo, immediately after slabbing. Slabs were made available for viewing and sample selection.

3. Samples 1-1/2" in length were drilled from bulk portion using liquid nitrogen on a one per foot basis.

4. Samples were packaged using aluminum foil and end screens. Package was seated to sample at 200 psi.

5. Samples were extracted with Dean Stark extraction equipment for two days using toluene solvent.

6. Samples were transferred to azeotrope solvent for additional cleaning. Azeotrope was monitored until clean.

7. Samples were dried in vacuum oven at 60 C until weights stabilized.

8. Samples were vacuum saturated with dewatered and deaerated toluene and pressure saturated at 1000 psi.

9. Liquid saturated porosity and grain density were determined and saturations calculated.

10. Nitrogen air permeability was measured at a confining stress of 200 psi.

SAMPLE INVENTORY, TRANSFER, AND SHIPMENT SUMMARY

1. Bulk core was shipped to Bellaire Research Center June 20, 1986.

2. Geologic portions are stored at Petroleum Testing Service storage facility.

3. Cores #1 and #2 of sponge core are stored at Petroleum Testing Service storage facility.

Shell California Production Inc.

CORE RECORD

("HEAVY" OIL PROVINCES)

AREA OR FIELD

COMPANY SCPI

LEASE AND WELL NO. 4-1

NO.	FROM	TO	RECOVERED	Rock type, color, stratification, hardness and cohesion, other features, e.g., fossils, cements, clay occurrences, carbonaceous material, dip, odor (oil / H_2S), GRA grain size (range and predom. size), silt and clay content, sorting, grain shape, est. of porosity, perm, and saturation.	OIL SATURATION OBSERVATIONS					SHOW SYMBOL	LITH. SYMBOL
					SAMPLE DEPTH	VISIBLE OIL: LIQ. OIL STR. OR GLO. A.M.S.*	VISIBLE OIL: STAIN ONLY A.M.S.*	COLOR OF FLOUR.	COLOR OF CUT AND NUM.		
5	8538	8566	9.2	Sandstone, med. gry brn to grey; appar. massive bedding; firm to sl. friable, gry rock v. hd; lt. brn. oil stain at top, decr. in lower half, with incr. hardness. Fair to wk. petrol. odor; dom sl. to non-calc, becoming extr. calc in grey rock from 8543.8 to 8545.8. Natural fractures at 8541.9, 8542.5, 8542.7, 8544.5, 8544.6, several fractures filled w/calcite in tight streak. Two breaks between pieces in the tight section are obvious fracture surfaces with slickensides, calcite and gypsum lining. Sampled segment at 8545.7 also contains Reidel shears in opposing directions. Core partially rubble, but several contiguous segments are present: 8538-8541.1, 8542-42.8, 8543.8-45.8. One rubble piece at 8546.1 prob. belongs at 8545.8. Cement dom sl. to non-calc in upper core, abruptly becoming extr. calc. at diagenetic boundary at 8544.8: Sandstone on either side of irregulare cementation front. GRA: VF to CRS often VF to MED, dom MED; fair to poor sort; ang. to sbang. dk. grs. sbrnd; composition: dom clr to milky qtz, fspar ranges from occ. to com; common dk mafics & lithic frags; tr. glauc. or chlorite; grain supported matrix with silicic cmt, cmt incr. with depth. Cmt becomes calc. at 8544.8; "fault" gouge on fracture surfaces 8545 contain calcite and gypsum; sands without calc cmt. show fair to good porosity and perm. Flourescence: sample flour. varies from patchy to v. intense yel., pale yel. in tight strk; instant to fast blooming grn-yel cut flour, pale grn crush flour only in tight streak. vis. cut amber to dk amber.	8539.1		S	Uneven lt. to mod. Brt.yel	Amber	2	S
					8541.5		S	Brt.yel			
					8542.9		S	Intense brt yel	Amber	2	
					8545		Abs	Pale yel		0	
					8547		M	Intense to pale yel	Dark amber	2+	
				Cores 3, 4, 5 all show common fracturing, prob. grain shearing. Some fractures are filled, but most may be permeable. Some vugular porosity within fractures was observed. Core recovery was too poor to do meaningful fracture density study.							
				PTS labelled last tray (8544.3-8547.1) upside down. Lab measurements are at correct depths, but core photo is wrong. Tight streak is at top (8544.3).							

SYMBOLS: C-CLAY OR SHALE (SAND 0-5%). I-CLAY OR SHALE WITH SAND STREAKS (SAND 5-25%). 2-CALY OR SHALE AND SAND (SAND 25-60%). 3-SAND WITH SHALE STREAKS (SAND 60-90%). S-SAND (90-100%). NOTE: SHOW FLUID CONTENT AS IN STANDARD LEGEND. *A =ABUNDENT M = MODERATE S = SPARSE

Mr. Jay B. Wharton
c/o Belridge Oil Company
McKittrick, California

Dear Sir:

I am sorry that I have been delayed in giving you the necessary data covering your Well 7-1 in the Belridge oil field. However, I have made my investigation and the conclusions and opinions herewith given may be of some value to you.

A minute inspection of the core samples revealed that the interstices were practically completely sealed off with a secondary cementing material, which reacted to acid treatment. After discovering this condition, I requested Mr. Roy Barnes, of the Continental Oil Company, to give me some of the core samples from the offset well, Result No. 4, in order to ascertain if this secondary cementing material would be found in the core samples of the Result well. Mr. Montgomery, field engineer for the Continental Oil Company, selected core samples which were presumed to correspond to the stratigraphic position in the Result well of the samples that you sent me. These were thoroughly inspected and clearly showed that there was no secondary cementing in the interstices of the core samples from this well. The cementing material found in the samples of your well is clearly a carbonate material and is undoubtedly from the mud which you used in drilling the well, in view of the fact that you informed me that you did use a mud containing a high lime content. The action of a colloidal lime material is oft times very peculiar. It has been frequently pointed out by various scientists that colloidal systems are mainly characterized by their extreme development of surface and surface boundaries. It has also been mentioned that in such boundaries there are energies typical thereto, which are generally designated as boundary energies. Whereas classical chemistry defines the properties of a system by the properties of its mass, we find that the properties of colloidal systems are primarily governed by those of the developed surface. The colloidal state differs in respect to the surface development of its systems from matter in the coarse state, or "hetrogeneous systems", by reason that in the latter case the boundary-surfaces are smaller and, therefore negligible compared to the mass, whereas in colloidal systems it is just the reverse. The boundary-surface energies manifest their presence in various ways, generally known as capillary phenomena. The study of these special properties of boundary-surface layers or of extremely thin layers of matter, is the subject of capillary physics and chemistry.

8000274639

1229 Bartlett Building
Los Angeles, California

One of the most important phases covering the use of colloids, and particularly a lime colloid, is the adsorption phenomena and the capillary condensation. Undoubtedly, the most important of all adsorption phenomena in respect to the drilling of oil wells, are those taking place in solid-liquid interface. Such a phenomena at its best is extremely complex. The phenomenon that a pure and true solution, being brought in contact with an insoluble substance is tenaciously retained on the surface of the solid, is generally known as lyosorption. The wetting of a solid body is the simplest example of this phenomena. According to one scientist, the adsorption layer thus formed is termed lyosphere. The lyospheres are to be considered as diffuse so that a continuous transition exists between them and the interior of the surrounding liquid. Experiments on sedimentation volumes of comparatively coarse suspensions in different liquids, as carried on by W. O. Ostwald and W. Haller, A. B. Buzagh, H. Freundlich, H. L. Rodder, and E. A. Hauser, seem to prove that the thickness of the lyosphere is, contrary to previous assumption, far in excess of normal molecular dimension. The thickness of the lyosphere seems to depend on the type of adsorbing surface and on the liquid and nature of the colloid present. It has been ascertained that lyosorption is exceptionally pronounced with such substances as can be considered as extremely heteropolar, e.g., more of the silicates. This leads to the assumption that the development of a lyosphere depends to a large extent upon the residual electro-static valencies of the adsorbent. This results in the important conclusion that lyosorption can be very materially influenced by changes in the charges of the adsorbing surface. With increasing charge, lyosorption must also increase. In general, liquids of high dielectric constant will show lyosorption to a smaller degree than those of a low dielectric constant. Generally speaking, when colloidal systems are involved, the term lyosorption is more commonly referred to as solvation, or hydration.

The study of colloidal dispersion is extremely complex and, needless to say, unless many factors are known about the colloid that is used in a drilling mud, it is dangerous to arbitrarily make use of an unproven substance. I have referred before, in connection with this discussion, to polar adsorption. It is a known fact that when solid-liquid systems are involved, such as a colloidal system, only one constituent is really adsorbed, whereas the other remains in solution. Since the electric neutrality of the system as a whole must be maintained, another ion must be substituted. This ion can be either given off by the adsorbent

1229 Bartlett Building
Los Angeles, California

in exchange for one taken on, or it must be obtained by a secondary reaction in the dispersion medium. This phenomenon is generally known as exchange adsorption, or ion exchange reaction. The most typical instance of this phenomenon is the so-called base exchange of zeolites or permutites, as are being used with increasing success for water softening purposes. The zeolites correspond generally in their chemical constitution to the clays. They are very open-textured, aluminum hydro-silicates. The oxygen atoms present in the surfaces or at the edges or corners of the crystal lattice possess residual electro-static fields. These are satisfied by available cations, such as sodium. If such a zeolite is brought into contact with water containing calcium salts, the calcium ions will be adsorbed, and the sodium ions given off.

In the foregoing discussion, I have merely called to your attention some of the factors surrounding the use of a colloidal material that penetrates a porous media, such as an oil-saturated formation. From the study of colloids and colloidal dispersions, we do know that various phenomenon take place, and that such colloidal suspensions are very often ionized to provide deposition of materials in the adsorbing media. I am of the opinion that the use of a mud having high lime content, used in the particular formations which you are attempting to produce, results in a deposition of this lime in the small interstices and capillaries of the formation, thereby effectively sealing them off from the transmission of fluids. The core sample submitted from your 7-1 well clearly revealed that there has been a secondary deposition, and that such was not the case in the well drilled by the Continental Oil Company on the offset location, their Result No. 4.

We made porosity and permeability determinations on all of the samples submitted to us, the results of which are herewith given.

Depth	Porosity %	Permeability Millidarcy's
8165	11.96	17.8
8176	14.78	4.7
8182	14.04	8.2
8193	13.54	6.3
8200	12.41	5.0
8221	13.65	7.1
8224	12.58	6.6
8230(A)	17.44	600.97
8230(B)		694.0
8230(C)	17.82	704.0
8230(D)	17.05	662.0
8231	11.18	10.6

1229 Bartlett Building
Los Angeles, California

The sample from 8230 feet gave an extremely high permeability and the laboratory made several re-runs upon this particular sample in order to make certain that their findings were correct. It is quite apparent that this particular formation was not as tightly sealed as the other formations. It is entirely possible that you can arrange to produce this particular formation and exclude the others. There would undoubtedly be, beyond the limits of the well core, a vertical and horizontal migration, which would enable you to obtain a rather high recovery from this particular formation, even though it is relatively thin.

As previously stated, samples were taken from the Result No. 4 well and subjected to porosity and permeability determinations, the results of which are herewith given.

Depth	Porosity %	Permeability Millidarcy's
8200	10.18	5.7
8215	15.64	34.0
8220	9.59	2.5
8227	12.12	2.7
8235	18.31	74.6
8256	11.07	2.0
8259	16.36	92.8
8265	16.64	135.0
8266	16.82	100.0

I trust that the information given to you in this discussion will be of some value. I do not believe that it is wise for you to use a mud containing a lime colloid. It is quite apparent that such a material is adsorbed by the formations which you are drilling. It is very doubtful if you can offset this deposition by subsequent acidizing as there is insufficient capillary volume to allow the penetration of the acid to any degree into the formation. In the present well, you might be able to obtain satisfactory production from the thin layers at 8230 feet. At least, it has sufficient permeability, but I am not acquainted with its saturation characteristics. I do not believe you would be able to effectively remedy the present well without coming back up the hole and redrilling that portion of the hole that enters the producing formations. I do not believe that the deposition of lime material has penetrated very deeply into the formation from the well bore, and the new well bottomed a few feet away from the present bottom would enable you to core an entirely clean section free from lime contamination.

1229 Bartlett Building
Los Angeles, California

I hope that this investigation has been of some use to you. The opinions expressed in this letter are based upon the laboratory investigation made upon the samples submitted. Unfortunately, the samples as submitted, were not freshly taken from the core barrel and some of the deposition in the interstices might have taken place by the subsequent evaporation of the connate water, which would contain some of the suspended colloids. I do not believe this to be the case, however. I am more inclined to think that there was an effective sealing of the interstices by ion exchange of the colloid system, which was used in the drilling mud.

Very truly yours,

Graydon Oliver

July 11, 1940

Belridge Oil Company
McKittrick, California

Attention of Mr. J. B. Wharton

Gentlemen:

The results of core analysis on your well 7-1, North Belridge Field, Kern County, California are given for each point analyzed in the attached, tabulated data.

On the final page of this data are given summary figures for the distillate productive zone from 7973 feet to 8173 feet and for the oil productive zone from 8173 feet to 8230.5 feet. Average connate water saturation data are shown for two sections of the distillate zone, and recovery figures are given in columns three and four for the oil zone. Since these summary figures are applicable to sections represented by recovered core, they may be changed, if the adjacent sections of lost core prove oil productive, to correspond with the increased thickness of permeable formation.

Completion should be made sufficiently below the gas-oil contact at 8173 feet to avoid gas coning. As shown on the summary sheet, the productive capacity (feet of permeable sand thickness times average permeability) for the recovered part of the second oil zone is approximately the same as for the recovered part of the upper oil zone.

The numbers in parentheses on the summary sheet refer to footnote remarks.

Enclosed please find our original Coregraph and Van Dyke Negative. Additional prints may be made from either the original or the Van Dyke Negative; the latter, being unaffected by handling and use, is enclosed for your permanent records.

Very truly yours,

CORE LABORATORIES, INC.

Coring

355-357 Recovered 3 inches - 13%
Extremely hard calcareous sandstone, medium with some coarse grains. Glauconite and oolites scattered throughout. Few small and unidentifiable shell fragments.

357-361 Recovered 12 inches - 25%
Top 10" - same sandstone, but coarser. More fossils - cross sections of what appears to be a very small Echinoid (Scutella merriami?). Also one questionable small Pecten. No mica.
Bottom 2" - hard gray fine calcareous sandstone and calcareous siltstone and one small piece dark gray siliceous limestone.

361-365 Fishtail. Cuttings = small chips of fine to medium dark gray to light gray sandstone.

365-365'4" Recovered 1 inch - 25%
Extremely hard gray medium to fine calcareous sandstone. No mica.

365'4"-365'10" Recovered 2 inches - 33%
Extremely hard coarse gray calcareous sandstone. Suggestions of fossils. No mica.

365'10"-366'6" Recovered 4 inches - 50%
Extremely hard gray medium grained calcareous sandstone. Scattered oolites and glauconite grains.

366'6"-373'6" Recovered 2 inches - 3%
Extremely hard rather dark gray highly calcareous ill-sorted sandstone with grains varying from fine to granule size. Fossiliferous but fossils are not idenfifiable. No mica.

373'6"-376' No recovery.

376-379 Recovered 2 inches - 5%
Extremely hard gray fine to medium calcareous sandstone, scattered oolites, glauconite, and small fragments that appear to be shell fragments. No mica.

379-380'4" Recovered 5 inches - 31%
Same sandstone. Oolites and few glauconites - no mica.

380'4"-393 No recovery.

393-396'8" Recovered 3 inches - 7%
Extremely hard gray calcareous granuliferous sandstone. One small shell fragment. No mica.

396'8"-397'2" Very hard - no recovery.

Type of Extraction - Dean Stark Toluene Extraction.
Confining Pressure on the Permeameter = 200 psi
Oil Gravity Estimated By Visual Fluorescence = 35 API

These results must be used with caution. Sidewall core samples are obtained by impact coring. This method can fracture hard formations, thereby possibly increasing the porosity and permeability. In soft formations, impact coring can compact the samples, resulting in decreased porosity and permeability.

Drilling mud may penetrate fractures and soft formations, thereby affecting the porosity, permeability, fluid saturation, grain density and cation exchange capacity results.

Paleontologic summary of Belridge Oil Company 23X-35, Sec.35-27S-20E, MDB&M; Kern County, California.

Belridge Oil Company
c/o Mr. Joseph A. Dunwoody

3790-4730	Upper Miocene - Bolivina vaughani Zone equals Antelope (McLure) and Stevens sands.
3790-3820	(ditch) Uvigerina subperegrina fragment, Haplophragmoides sp. common, Coscinodiscus sp. rare and radiolaria rare.
3850-3880	(ditch) Uvigerina subperegrina fragment, Haplophragmoides sp. common and radiolaria rare.
3910-4000	(2 ditch) Haplophragmoides sp. abundant.
4030-4060	(ditch) Haplophragmoides sp. common, radiolaria rare and pyrite few.
4090-4120	(ditch) Globigerina bulloides rare, Haplophragmoides sp. common and radiolaria few.
4150-4180	(ditch) Haplophragmoides sp. abundant and Globobulimina pacifica rare.
4210-4240	(ditch) Bulimina sp. rare and Haplophragmoides sp. common.
4270-4300	(ditch) Bulimina cf. ovata rare and Haplophragmoides sp. abundant.
4330-4360	(ditch) Bulimina cf. ovata rare, Haplophragmoides sp. abundant and light tan sporbo rare.

4390-4420	(ditch) Haplophragmoides sp. abundant and light tan sporbo rare.
4450-4480	(ditch) Haplophragmoides sp. abundant.
4520-4610	(2 ditch) Haplophragmoides sp. abundant and light tan sporbo rare.
4640-4670	(ditch) Haplophragmoides sp. abundant.
4700-4730	(ditch) Haplophragmoides sp. rare and small sporbo common.

4760-5560± Upper Miocene. Pulvinulinella gyroidinaformis Zone equals MacDonald.

4760-4790	(ditch) Uvigerina cf. hootsi rare, Virgulina californiensis few and Buliminella subfusiformis rare.
4820-4850	(ditch) Uvigerina cf. hootsi few, Nonion costiferum rare, Valvulineria miocenica few, Valvulineria cf. obesa rare and Bolivina cf. advena rare.
4870-4900	(ditch) Valvulineria miocenica rare, Bolivina advena rare and Haplophragmoides sp. abundant.
4930-4960	(ditch) Valvulineria miocenica rare, Uvigerinella sp. rare and Haplophragmoides sp. abundant.
4990-5020	(ditch) Haplophragmoides sp. abundant and Virgulina californiensis rare.
5050-5080	(ditch) Haplophragmoides sp. common and fine sand common.
5110-5140	(ditch) Haplophragmoides sp. common.

5170-5200 (ditch) Uvigerina cf. hootsi rare, Valvulineria miocenica rare, Valvulineria cf. californica obesa rare, fish remains rare and Haplophragmoides sp. common.

5230-5260 (ditch) Haplophragmoides sp. few and fine sand common.

5290-5320 (ditch) Haplophragmoides sp. few, indeterminate Mollusk fragments common, sporbo few and fine sand common.

5350-5380 (ditch) Haplophragmoides sp. rare, sporbo few, indeterminate Mollusk fragments common and fine sand common.

5410-5440 (ditch) Similar to last above but with Mollusk fragments and sand more common.

5470-5560 (2 ditch) Indeterminate Mollusk fragments rare, sand common and "lost circulation material" abundant.

5590-6280 Undifferentiated Middle Miocene equals undifferentiated Valvulineria californica (Devilwater) - Siphogenerina branneri (Gould-Buttonbeds-Temblor) Zone.

5590-5620 (ditch) Valvulineria californica gens few, Valvulineria depressa rare and Robulus smileyi rare.

5650-5680 (ditch) Valvulineria californica ? rare, Nonion costiferum rare and Bulimina ovata rare.

5710-5740 (ditch) Pullenia cf. miocenica fragment and Haplophragmoides sp. common.

5770-5800 (ditch) Haplophragmoides sp. few and gray sporbo common.

5830-5920	(2 ditch) Cement ? fragments few and gray sporbo common.
5950-5980	(ditch) Haplophragmoides sp. few and sporbo common.
6010-6100	(2 ditch) Nonionella miocenica rare, Haplophragmoides sp. few and sporbo few.
6130-6160	(ditch) Haplophragmoides sp. common.
6190-6220	(ditch) Barren sand. Probably Button bed (Temblor) sand.
6250-6280	(ditch) Indeterminate fossil fragments rare and sand clusters few.

6280-7060 Lower Miocene - Saucesian equals Media shale and Carneros sand.

6280-6310	(ditch) Robulus cf. warmani rare, Nonion costiferum rare, Haplophragmoides cf. trullissata rare and pyrite few.
6340-6370	(ditch) Haplophragmoides sp. fragments few, pyrite few and sporbo rare.
6400-6430	(ditch) Similar to last above.
6460-6490	(ditch) Nonionella sp. rare, Haplophragmoides sp. fragments few, Globigerina bulloides rare, pyrite few and sporbo few.
6520-6550	(ditch) Robulus cf. warmani fragment, Uvigerinella sp. rare, Nonion costiferum rare, Haplophragmoides sp. rare and sporbo few.
6580-6610	(ditch) Robulus warmani rare, Nonion costiferum rare, sporbo few and kaolinitic sand few.

	6640-6670	(ditch) Cyclammina obesa rare, Nonionella sp. rare, fish remains rare and sporbo few.
	6700-6730	(ditch) Robulus sp. rare, Gyroidina soldanii rare, Nonion costiferum rare, sporbo few and pyrite few.
	6760-6790	(ditch) Haplophragmoides sp. rare and ill-sorted kaolinitic sand common.
	6820-6850	(ditch) Robulus warmani rare, Haplophragmoides sp. few, Cyclammina obesa rare and sand as last above few.
	6880-6910	(ditch) Siphogenerina transversa few, Robulus warmani common and Cyclammina obesa rare.
	6940-6970	(ditch) Siphogenerina transversa few, Robulus warmani abundant and Haplophragmoides sp. rare.
	7000-7030	(ditch) Robulus warmani rare and Uvigerinella sp. rare.
	7030-7060	(ditch) Robulus warmani rare.
7090-7210	Lower Miocene. Saucesian equals Upper Santos.	
	7090-7120	(ditch) Siphogenerina tenua rare, Valvulineria "turbinatus" rare and sporbo abundant.
	7120-7150	(ditch) Siphogenerina tenua abundant, Valvulineria "turbinatus" few, Robulus warmani rare, glauconite rare and sporbo few.

	7150-7180	(ditch) Siphogenerina transversa few, Siphogenerina sp. (phosphatic) few, Uvigerinella parva common, Gyroidina soldanii rare, Robulus simplex rare and sporbo few.
	7180-7210	(ditch) Siphogenerina transversa rare, Robulus warmani rare, Valvulineria "turbinatus" rare, glauconite common and sporbo common.
7210-7300	Lower Miocene. Possibly Upper Zemorrian equals "Middle" Santos.	
	7210-7240	(ditch) Siphogenerina cf. transversa (phosphatic) rare, Bulimina cf. carnerosensis ? rare, Robulus warmani rare and sporbo common.
	7270-7300	(ditch) Siphogenerina cf. transversa few, Siphogenerina sp. (phosphatic) rare, Robulus simplex rare, Cyclammina obesa few, glauconite few and sporbo few.
7330-8670	Lower Miocene. Lower Zemorrian equals undifferentiated Lower Santos - Bloemer - Belridge 64.	
	7330-7360	(ditch) Siphogenerina nodifera few, Nodosaria anomala rare, Robulus warmani rare, glauconite few and sporbo few.
	7390-7420	(ditch) Uvigerina cf. atwilli few, Robulus warmani rare and Cyclammina obesa rare.
	7450-7480	(ditch) Uvigerina cf. atwilli rare, Siphogenerina sp. rare, Robulus warmani rare, Uvigerinella "belridgensis" rare and glauconite few.

7510-7540	(ditch) Robulus warmani rare, Siphogenerina sp. fragment, sporbo abundant, glauconite abundant and pyrite common.
7570-7600	(ditch) Indeterminate Mollusk fragments few, sporbo few and kaolinitic sand common.
7630-7660	(ditch) Uvigerina cf. atwilli rare, Siphogenerina sp. rare, Ostracoda rare, indeterminate Mollusk fragments rare and sand as last above few.
7690-7720	(ditch) Siphogenerina sp. fragment, sporbo abundant, glauconite rare and sand common.
7750-7780	(ditch) Uvigerina cf. gesteri crushed single specimen, sporbo abundant, glauconite common and sand common.
7790-7810	(ditch) Siphogenerina sp. (phosphatic) rare, sporbo abundant, "glauconitic grit" common and pyrite few.
8140-8170	(ditch) Siphogenerina cf. transversa few, Cyclammina sp. fragments rare, sporbo common and glauconite common.
8230-8260	(ditch) Gyroidina soldanii rare, Uvigerina cf. atwilli fragment, Cyclammina obesa rare, sporbo few and glauconite rare.
8290-8320	(ditch) Siphogenerina sp. fragment, Cyclammina obesa few, Cyclammina incisa rare, sporbo few, glauconite few and ill-sorted sand common.
8330-8345	(ditch) Cyclammina sp. rare, Haplophragmoides sp. (coarsely arenaceous) rare, sporbo few, glauconitic grit common and fine sand common.

8370-8400	(ditch) Uvigerina atwilli rare and sporbo common.
8430-8460	(ditch) Uvigerina atwilli rare, Siphogenerina sp. rare, Haplophragmoides sp. rare, sporbo common and glauconite few.
8520-8550	(ditch) Uvigerina atwilli rare, Robulus warmani rare, Cyclammina ? sp. fragments few, sporbo few and sand few.
8580-8610	(ditch) Cyclammina incisa few, Robulus warmani rare, Siphogenerina transversa rare, sporbo few and glauconite rare.
8640-8670	(ditch) Dentalina sp. rare, sporbo few and glauconitic sand common.

8700-8890± Oligocene. Uvigerina cocoaensis Zone equals Tumey (Wagonwheel).

8700-8730	(ditch) Uvigerina atwilli common, Uvigerina sp. few, Bulimina sculptilis few, Nodosaria ? chambers few and Gyroidina soldanii rare.
8740	(sidewall) Nodosaria sp. chambers few, Haplophragmoides cf. trullissata rare, Cyclammina spp. few and Bathysiphon sp. few.
8760-8790	(ditch) Uvigerina atwilli rare, Bulimina sculptilis rare, Cyclammina sp. few, Bathysiphon sp. few and glauconitic sand abundant.
8820-8850	(ditch) Uvigerina atwilli rare, Cyclammina sp. common and Nodosaria ? chambers few.
8840	(sidewall) Indeterminate fossil fragments few.

8880-8900	(ditch) Cyclammina sp. common, Robulus sp. rare, Uvigerina cf. atwilli rare and glauconite few.

8898-9000 Possibly undifferentiated Upper Eocene equals possible undifferentiated Kreyenhagen.

8898	(sidewall) Haplophragmoides sp. common, sponge spicules few, small pyritized radiolaria rare and glauconite few.
8907	(sidewall) Cyclammina sp. rare and Bathysiphon sp. rare.
8930-8960	(ditch) Cyclammina sp. common.
8950	(sidewall) Fish remains rare and small pyritized radiolaria rare.
8960-8990	(ditch) Haplophragmoides sp. common, sponge spicules rare, pyritized radiolaria few and pyrite common.
8970	(sidewall) Pyrite rare.
8990-9000	(ditch) Haplophragmoides sp. few, Bathysiphon sp. few, pyritized radiolaria rare, pyritized plant spores rare, pyritized sponge spicules rare and pyrite common.

Sincerely,

R. Stanley Beck

HALLIBURTON SERVICES
DUNCAN, OKLAHOMA

LABORATORY REPORT

No. T11-A240-85

To Mr. Mike Eberhard
Halliburton Services
Bakersfield, CA

Date December 21, 1985

This report is the property of Halliburton Services and neither it nor any part thereof nor a copy thereof is to be published or disclosed without first securing the express written approval of laboratory management; it may however, be used in the course of regular business operation by any person or concern and employees thereof receiving such report from Halliburton Services.

We give below results of our examination of one formation core sample.

Submitted by Shell E & P

Marked Well: 43-27
Location: North Belridge, Kern County, CA
Formation: Upper 64 "U" Sand
Depth: 8,727 feet
Samples Received: December 9, 1985
Los Angeles Division Reference No: CBB-A98-0394-0822-85

Purpose

The purpose of this report is to analyze the submitted samples. The tests include rock properties, and a permeability and porosity measurement.

Discussion

The results of the requested tests are included in the Data Section of this report.

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose merchantability or otherwise, as to the accuracy of the data reported.

Data

Permeability and Porosity Analyses

Purpose: To measure the permeability and porosity of a porous media.

Procedure: A test plug 1 inch in diameter by 1.187 inches long is obtained from the submitted core sample so that the longitudinal axis of the plug is normal to the depth. The plug is then oven dried and allowed to cool to room temperature.

Permeability is determined by placing the plug securely in a Hassler Sleeve of the Permeameter. Dry air is then flowed through the plug. Measurements of flow rate and pressure drop across the plug are then obtained.

Porosity is determined by placing the plug securely in a Hassler Sleeve of the Porosimeter. The system is purged with helium gas. The meter has a known storage volume in which the helium gas is allowed to reach equilibrium, a reference point is set on the gauge and a reading taken. The valve to the plug chamber is opened allowing the helium gas to expand into all the void spaces of the plug. A gauge reading is taken in cubic centimeters. The plug is removed and a nonporous plug is placed in the holder. The gas volume is measured in the same manner as the sample plug. The difference in the volumes is the pore volume of the test plug. The bulk volume is calculated from measuring the plug with calipers.

Results: $$\text{Permeability (md)} = \frac{C\,Q\,L}{0.7845\,(D)(D)}$$

$$\text{Porosity (\%)} = \frac{P.V.}{B.V.} \times 100$$

C is the constant taken from the Permeameter calibration charts.
Q is the flow rate in cubic centimeters per second (cc/sec).
L is the plug's longitudinal length in centimeters (cm).
D is the diameter of the plug in centimeters (cm).
P.V. is the pore volume measured in cubic centimeters (cc).
B.V. is the bulk volume measured in cubic centimeters (cc).

Sample No.	Depth (feet)	Porosity (%)	Air Permeability (md)
1	8,727	12.6	0.5

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Data Cont'd

Rock Properties Tests

Purpose: To measure the elastic deformation and strength of rock materials.

Procedures: A 15/16 inch diameter by 2 inch plug is drilled horizontally from a core and placed in the test load cell. An axial stress is applied to the plug and the resulting deformation is measured by displacement transducers. Two transducers are mounted to detect axial strain and one transducer to detect lateral strain. Measurements are taken on the first flat portion of the stress-strain curve. This is prior to permanent rock deformation, i.e. in the elastic limit of the sample. This varies with the properties of the sample. For compressive strength measurements the axial stress is applied to the test plug until full scale (120,000 lb) is reached or failure occurs.

Results: This data is recorded as Young's Modulus, which is the ratio of stress to strain for values of stress not exceeding the elastic limit of the test plug. Poisson's Ratio is the ratio of lateral strain to axial strain within the elastic limit of the test plug.

Sample No.	Depth (feet)	Young's Modulus (psi)	Poisson's Ratio
1	8,727	1.4E6	0.22

NOTICE: This report was prepared by and is the property of Halliburton Services, a Division of Halliburton Company; the data reported, intended for the private information of the above named party, is limited to the sample(s) described; accordingly, any user of this report agrees that Halliburton shall not be liable for any loss or damage, regardless of cause, including any act or omission of Halliburton, resulting from the use of the data reported herein; and Halliburton makes no warranties, express or implied, whether of fitness for a particular purpose, merchantability or otherwise, as to the accuracy of the data reported.

Remarks

The data in this report were given to Mr. Mike Eberhard by Mr. Mark Parker during a telephone conversation on December 19, 1985.

Core Sample Disposition

The core samples will be held in storage for 60 days following mailing of the report. At the end of this time, we will select representative core pieces for storage in the Core Library and discard the remainder unless we are requested to ship the cores to another location.

The selected core pieces will be in the Core Library for two years and will be considered the property of the customer. These core pieces will not be released without the permission of the customer, the originating Halliburton Engineer, or a Stimulation Engineering and Design Section Supervisor. After two years, the selected core pieces will be kept for another eight years, during this time the pieces may be used for a variety of projects.

Data Book Reference

The data presented in this report are recorded in Stimulation Engineering and Design Book No. 5842, page 68; and Reservoir Research and Engineering Book No. R112, page 8.

cc: Mr. J. B. McCalla, Jr.
Mr. J. R. Fehrenbach
Mr. J. E. Diller
Mr. R. M. Melton
Mr. R. M. Lasater
Mr. A. B. Waters
Dr. L. E. Harris

Respectfully submitted,

Laboratory Analyst

SCPI WELL 43-27

cores 5-9

ANNOTATED

AUG 24 2010

Performed by:

Petrophysical Services
1500 Salado Drive
Mountain View, CA 94043
(415) 960-0964

Approved by: _____ for

Dr. Carol Tosaya
Director, Laboratory

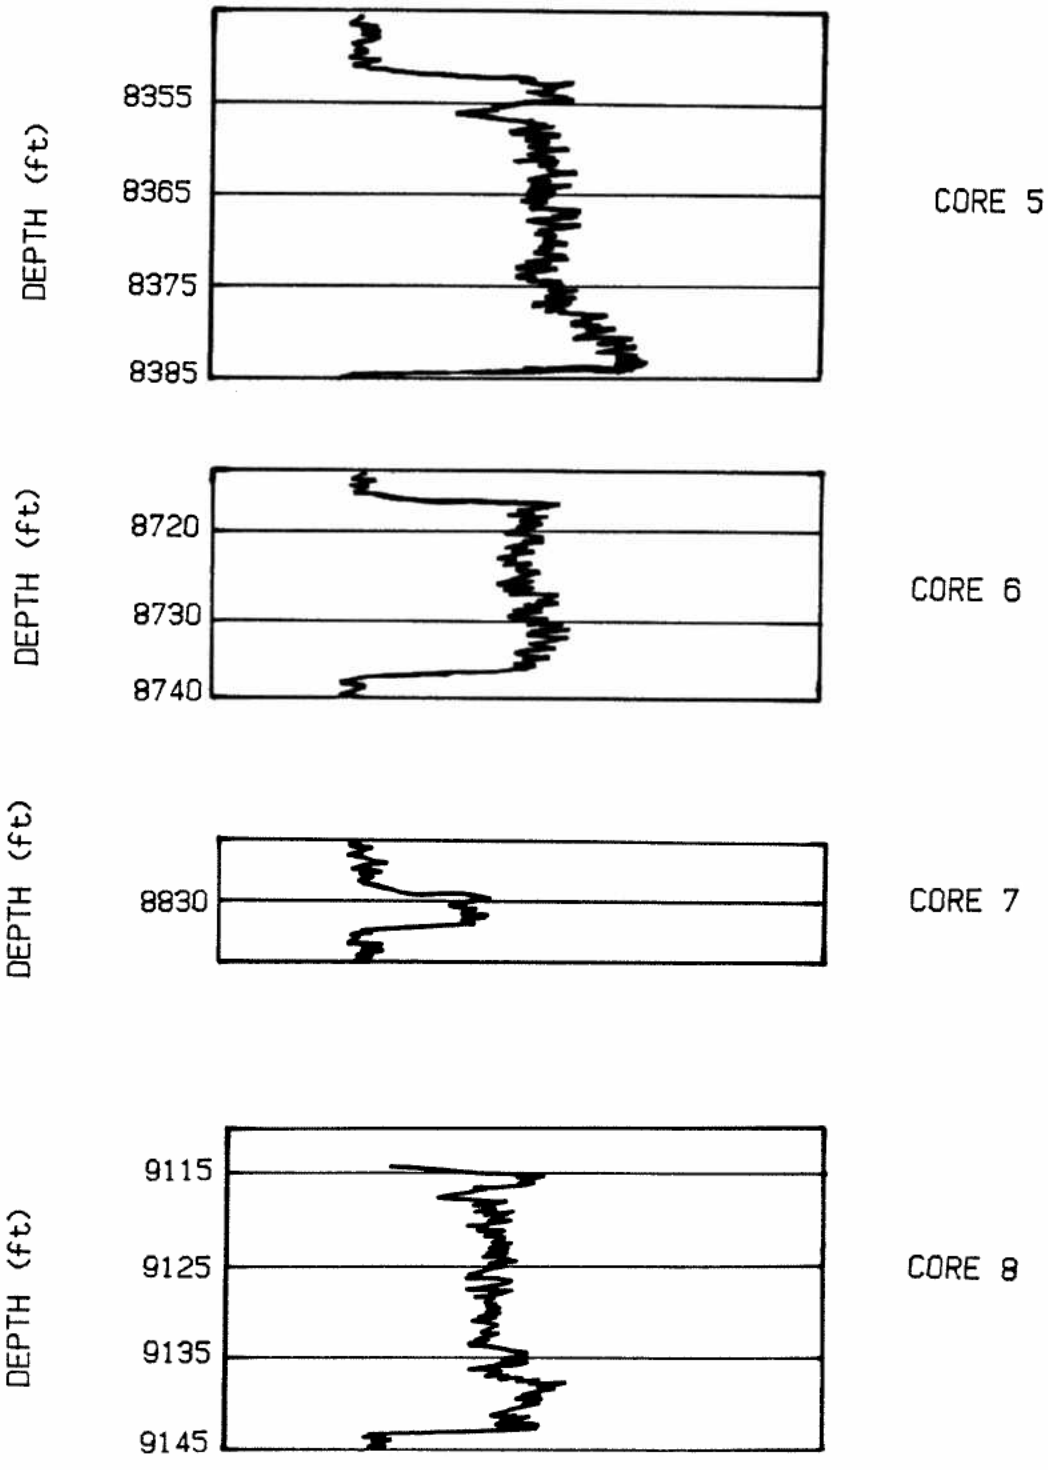
August 1985

382/8I

PROCEDURES

The refrigerated whole core was received and gamma scanned. The gamma scan data appears as Figure 1.

Next the core was slabbed 1/3 to 2/3. The 1/3 slab was photographed in color and UV light. Horizontal 1-inch diameter plugs were taken from the 2/3 slab at 1-foot intervals. Fluid saturation by the Dean-Stark technique, helium porosity, and gas permeability were measured on each sample. These data are presented in Table 1. Oil content was calculated as the difference in preserved and dry weight minus the weight of water removed in the Dean-Stark apparatus. It is presented as a volume percent saturation in Table 1 assuming a specific gravity of 0.85 for the oil.



Gas permeability at elevated pressure, liquid pore volume compressibility, and CEC were measured on selected samples. These data are presented in Tables 2, 3, and 4. All permeabilities in this report were measured by a transient technique with helium. The values given are the Klinkenberg permeabilities at effectively infinite pore pressure.

Pore volume compressibility was measured on samples saturated with 4.0 weight-percent NaCl.

CEC values were determined by the ammonium acetate method.

Photographs are provided in a separate volume.

Mr. M. A. Kopacz, Mgr. Geology
Rocky Mountain Division
Shell Western E&P Inc.
P. O. Box 576
Houston, TX 77001

Dear Mr. Kopacz:

SCPI, NO. 43X-27, KERN CO., CALIFORNIA

Pursuant to research agreements between our companies, we transmit the results of geochemical analyses on the subject well, as requested by M. Tynan. We are including copies of the report for distribution within your organization.

Very truly yours,

A N Fuller

For: D. G. Nussmann
Manager Geology

X-RAY DIFFRACTION ANALYSIS

AUGUST 1985 FILE #7825

AUG 24 2010

SCANNED

X-RAY DIFFRACTION RESULTS

Shale Slough: 9407-9471 feet. The shale consists primarily of clays. Tectosilicates are also present and include primarily quartz along with lesser amounts of plagioclase and potassium feldspars. Pyrite is also present as well as minor amounts of apatite and siderite.

The clay fraction consists primarily of mixed layer illite-smectite. The mixed layer clay is the random interstratified variety and contains 45% smectite (expandable) layers; therefore, the entire clay fraction contains about 32% expandible layers. Illite, kaolinite, and mixed amounts of chlorite are also present in the sample.

These results are semi-quantitative in nature because they are based on XRD peak intensity ratios. Variations in mineral chemistry (especially important in clays) cause variations in x-ray absorbance and consequent XRD peak intensities. Nevertheless, the results presented herein (shown on the following XRD table and pie charts) are significant.

Notes:
Company: VALLEY RESOURCES
Well: SHIDELER 1-28
Field: NORTH BELRIDGE
County: KERN
State: CA
Country: KERN
Depth provided in feet (ft) measured depth
True Mag - Dip magnitude in degrees (°)
True Azimuth - Dip Azimuth in degrees (°)
Dip Confidence:
E=Excellent(dip quality=1)
G=Good(dip quality=2)
F=Fair(dip quality=3)
P=Poor(dip quality=4 or 5)

SHELL CALIFORNIA PRODUCTION, INC.

PDET #43-27

CORE DESCRIPTIONS

Core #4

6067' SILTSTONE - medium gray; very hard; well indurated; low apparent porosity; very clayey; common very fine-grained sand; poor shaly partings; common micas; trace phosphatic material; very slightly calcareous; no cut fluorescence.

6065' 3" SANDSTONE - medium gray; lower very fine to lower fine; angular to subrounded; moderate to well sorted; spherical to subdiscoidal; very tight; hard; well indurated; good calcareous cement; low apparent porosity; absorbs water with great difficulty; silty; exhibits poor shaly partings; predominantly quartz; increasing feldspar and lithic grains; trace heavy minerals; slightly micaceous; weak yellow mineral fluorescence; no cut fluorescence.

6062' 4" SANDSTONE - medium gray; lower very fine to upper fine; subangular to rounded; spherical; moderately sorted; very tight; good calcareous cement; low apparent porosity and permeability; grain contacts often difficult to distinguish; slightly silty; predominantly quartz; scattered lithics and heavy minerals; trace biotite; breaks along weakly defined subparallel planes; no cut fluorescence.

6059' 4" SANDSTONE - medium to dark gray; lower very fine-grained; subangular; spherical to subprismoidal; poorly sorted; very silty; trace clayey; commonly grades to siltstone; occasional lenses of lower medium white to light gray sandstone; common calcareous cement; very hard; well indurated; tight; low apparent porosity and permeability; trace phosphatic material; predominantly quartz; trace micas and lithic grains; no cut fluorescence.

6056' 4" SANDSTONE - light to medium gray; upper fine to lower medium grained; moderately sorted; spherical and subdiscoidal; hard; well indurated; low to moderate apparent porosity; absorbs water with difficulty; common calcareous cement; common silty pods; generally structureless; predominantly quartz; increasing feldspars; minor micas and heavy minerals; no cut fluorescence.

6053' 4" SANDSTONE - light to medium gray; lower fine to upper fine grained; subangular to rounded; spherical; moderately sorted; very tight; well indurated; common calcareous cement; low apparent porosity and permeability; slightly silty; structureless; predominantly quartz; trace feldspars, biotite, and heavy minerals; common very well rounded, spherical, black lithic grains; minor pale yellow mineral fluorescence; no cut fluorescence.

6050' 4" SANDSTONE - light gray; lower fine to lower medium; subangular to rounded; spherical to discoidal; well sorted; strong calcareous cement; hard; well indurated; only slightly friable; low to moderate apparent porosity and permeability; predominantly quartz; trace feldspar; common heavy minerals and well rounded lithic grains; very slight trace micas; structureless; no cut fluorescence.

6047' 4" SANDSTONE - light to medium gray; lower fine to lower medium; subrounded; well sorted; spherical to discoidal; moderate apparent porosity; absorbs water with only slight difficulty; hard; moderate to well indurated; slightly friable; very weak calcareous cement; predominantly siliceous cement; well compacted; predominantly quartz; common feldspars; abundant heavy minerals; increased biotite; frequent well rounded black lithic grains; no cut fluorescence.

6044' 4" SANDSTONE - light to medium gray; upper very fine to upper fine; angular to subrounded; poorly sorted; subprismoidal to subdiscoidal; low apparent porosity and permeability; very tight; common calcareous cement; well indurated; hard; only very slightly friable; very silty; occasional patches of slickensided claystone inclusions; dirty appearance; predominantly quartz, common muscovite, scattered heavy minerals; structureless to slightly shaly in appearance; no cut fluorescence.

6041' 4" SANDSTONE - light gray; upper fine to upper medium grained; angular to subrounded; spherical to subprismoidal; well sorted; very slightly silty; friable; well compacted; moderate to well indurated; slight trace calcareous cement; predominantly quartz; common feldspar; trace biotite and muscovite; common heavy minerals and lithic grains; moderate to good apparent porosity; readily absorbs water.

Core #5

8353' SANDSTONE - light gray; hard; very fine to medium; angular; moderately sorted; tight and very calcareous; quartz, speckled with black mafics and lithics and possibly carbonaceous material; bright yellow mineral fluorescence; diffuse green-yellow cut fluorescence; weak green-yellow residual cut fluorescence; no visible cut.

8356' SANDSTONE - light gray to brown-gray; firm to slightly friable; fine to medium; subangular; spherical; moderately well sorted; decreased to slightly calcareous; kaolinitic; improved porosity, permeability, grain supported quartzose; scattered light to dark green glauconitic grains; occasional mica flakes; scattered soft, black, probably carbon grains; mottled to even yellow oil fluorescence; streaming green-yellow cut fluorescence; strong green-yellow residual cut fluorescence; very pale straw visible cut; apparent semisaturated with light oil.

8359' SANDSTONE - light brown-gray; hard to slightly friable; very fine lower to medium upper; angular to subangular; spherical to prismoidal; poor to moderate sorting; increasingly kaolinitic and micaceous; very slightly calcareous; quartz and feldspars; increasingly glauconitic and carbonaceous; light oil throughout; moderately strong yellow oil fluorescence; fast streaming green-yellow cut fluorescence; excellent blooming cut when crushed; very pale straw visible cut; fair petroleum odor.

8362' SANDSTONE - as above; increasing glauconitic grains; scattered black, soft, rounded grains; apparently structureless; good yellow sample fluorescence and green-yellow cut fluorescence; strong green-yellow residual cut fluorescence; fair petroleum odor.

8365' SANDSTONE - light brown-gray; firm and brittle, crushed with some difficulty; very fine lower to medium upper; dominantly angular; moderate sphericity; poor to moderate sorting; very slightly calcareous; kaolinitic; subarkosic; clear quartz, cloudy feldspars; scattered muscovite, glauconite; common black rounded grains, possibly carbonaceous; spotty to even yellow sample fluorescence on fresh surfaces; good green-yellow cut fluorescence and residual cut fluorescence; very pale straw visible cut; light straw visible dry ring; fair light oil odor.

8368' SANDSTONE - as above with increased brown coloration; increasingly argillaceous and silty; slightly increased friability; clay streaks nonfluorescent; overall good sample and cut fluorescence.

8371' SANDSTONE - light brown-gray; light brown oil stains; firm to hard; brittle; occasionally slightly friable; reduced apparent porosity and permeability; very fine to medium; angular; moderately sorted; quartzose; kaolin; increased brown clay lenses and matrix material; noncalcareous; glauconitic and micaceous; strong yellow oil fluorescence; streaming green-yellow cut fluorescence.

8374' SANDSTONE - as above; increasingly brown and argillaceous; noncalcareous; crushed with difficulty; still good yellow sample fluorescence; good green-yellow crush cut fluorescence; very pale straw visible cut; oil fluorescence washed away by solvent; oil fluorescence diminishes over time.

8377' SANDSTONE - gray-brown; firm to hard; occasionally slightly friable; very fine lower to medium lower; generally fining downwards with increasing clay/silt component; angular; poor to moderate sorting; noncalcareous; quartzose; common frosted to chalky feldspars; persistent glauconite and micas; yellow sample fluorescence confined to streaks and patches of less argillaceous sandstone; continued good green-yellow cut fluorescence and strong green-yellow residual cut fluorescence; cuts somewhat slower developing; reduced petroleum odor.

8380' SANDSTONE - gray-brown; slightly decreased induration; very fine to medium; subangular; spherical; moderately sorted; argillaceous; noncalcareous; silty; quartzose; slightly decreased glauconite, black grains; decreased sample fluorescence; weak green-yellow cut fluorescence; weak to moderate green-yellow residual cut fluorescence; no visible cut.

8383' 4" SANDSTONE - as above; increasingly argillaceous/silty; decreased to rare spotty yellow sample fluorescence; weak to diffuse green-yellow cut fluorescence; no visible cut; poor oil indicators overall.

Core #6

8717' SHALE - very dark brown to black; hard and dense; massive; micromicaceous sparkle on fresh surface; very silty; noncalcareous; top grooved by bit; no sample fluorescence; weak, slightly sweet petroleum odor; streaming green-yellow cut fluorescence; fair to good green-yellow residual cut fluorescence; no to pale straw visible cut fluorescence; no visible stain.

8720' SANDSTONE - light gray to light brown-gray; moderately hard; slightly friable; very fine upper to medium lower; subangular to subrounded; spherical to discoidal; moderate sorting; noncalcareous; kaolinitic; grain supported; occasional random argillaceous streaks; fair apparent permeability; arkosic; clear quartz and gray feldspars; trace scattered muscovite, biotite; rare light to very dark green, soft glauconite; trace dark mafics; 25 - 30% moderately strong yellow sample fluorescence; no to trace very light brown oil stain; slow streaming to diffuse green-yellow cut fluorescence, greatly enhanced with crush; fair yellow to green-yellow residual cut fluorescence; no to pale straw visible cut; weak petroleum odor.

8723' SANDSTONE - as above; slight decrease in sample fluorescence to 20%; patchy, spotty yellow oil fluorescence; weak green-yellow cut fluorescence; fair green-yellow residual cut fluorescence; no visible cut; weak petroleum odor; possible spotty very light brown oil stain.

8726' SANDSTONE - light gray, increased brown with increase in oil fluorescence; moderately hard with slight friability; fine lower to medium lower; angular to subrounded; spherical to prismoidal; well sorted; noncalcareous; light brown, kaolinitic matrix; grain supported; fair apparent permeability, water percolates slowly into dry surface; arkosic; quartz and feldspars; scattered muscovite, glauconite, biotite; slight trace mafics; calcareous patches; mottled with 50 - 60% moderately bright yellow oil fluorescence; good blooming green-yellow crush cut fluorescence; strong green-yellow residual cut fluorescence; light straw visible cut; very light brown dry residual ring; weak petroleum odor; best oil attributes of all core samples.

8729' SANDSTONE - as above; decreased to moderate sorting; increasingly argillaceous, brown streaks; calcareous in spots; 30% yellow oil fluorescence; slow green-yellow cut fluorescence, enhanced with crush; no visible cut; weak light oil odor.

8732' SANDSTONE - light gray-brown; moderately hard but individual grains easily scraped free; chips broken free from core fairly easily; very fine upper to medium lower; angular to subrounded; spherical to blocky; moderate sorting; dominantly noncalcareous with occasional calcareous patches; light brown to white kaolinitic matrix; slightly decreased apparent permeability; arkosic; clear quartz; gray to white feldspars; trace biotite; muscovite; trace glauconite; slight trace mafics; decreased oil attributes to 10% pale yellow sample fluorescence; weak green-yellow cut and residual cut fluorescence; no visible cut; no apparent visible oil stain.

8735' SANDSTONE - as above but slightly coarser; very fine upper to medium upper; poor to moderate sorting; calcareous patches; increased sample fluorescence to 35%; slow streaming, transparent to translucent green-yellow cut fluorescence; fair green-yellow residual cut fluorescence; no to very pale straw visible cut; weak light oil odor; overall core very homogeneous.

Core #7

8829' SANDSTONE - light gray; very fine to coarse; angular to subangular; very poorly sorted; moderate to very low sphericity; moderately well indurated; large fractures visible in core barrel; dominantly quartz with abundant gray feldspars and dark lithics, scattered mica; weakly calcareous in places; silica cement; moderate to strong petroleum odor; bright yellow to white-yellow sample fluorescence; greenish light straw visible cut; fast to instant, opaque, bluish green to blue-white cut fluorescence; very bright yellow residual cut fluorescence.

8832' 5" SANDSTONE - gray, white; very fine to coarse; angular to subrounded; very poor sorting; subspherical to prismoidal; well indurated; clear, white, amber quartz; feldspars, black lithics, occasional mica; silica cement; moderately calcareous in places; moderate petroleum odor; bright yellow to bright white-yellow sample fluorescence; greenish light straw visible cut; very strong, fast, streaming to instant opaque bluish green white to blue-white cut fluorescence; bright yellow-white residual cut fluorescence.

CORE #8

9115' SANDSTONE - fine to medium grained; moderately well sorted; spotty bright white-yellow mineral fluorescence with very diffuse cut fluorescence; moderate yellow-white residual cut fluorescence.

9117.67' SANDSTONE - fine to medium; fair apparent porosity; soaks in H20 less than 1/2 minute; even bright white-yellow sample fluorescence; fast diffuse white-yellow to greenish yellow cut fluorescence; no streamers; increased intensity with crush; no visible cut.

9120.67' SANDSTONE - as above; same cuts.

9123.67' SANDSTONE - as above; even bright white-yellow sample fluorescence.

9126.67' SANDSTONE - light gray; fine to medium; poor porosity; even bright white-yellow to greenish yellow sample fluorescence; cuts as above.

9129.67' SANDSTONE - as above; poor apparent porosity; patchy to even cuts.

9132.67' SANDSTONE - as above; patchy areas with no fluorescence; slightly brownish stain in these areas; fast very diffuse cut with increased intensity and occasional wispy streamers.

9135.67' SANDSTONE - fine to medium; poor apparent porosity; even bright greenish white yellow cut fluorescence.

9135.67' SANDSTONE - pale brownish gray; fine to medium; tight; no sample fluorescence; very faint greenish cut fluorescence; much less intense than above.

9141.67' SANDSTONE - dark brown-gray; argillaceous; tight; well indurated; trace very spotty very faint greenish sample fluorescence, probably contamination; fast greenish yellow cut fluorescence; transparent; very pale straw visible cut.

Core #9

9674' CALCARENITE - (Sandstone) - yellowish to pinkish gray-white; fine to coarse grains with scattered lith clasts; calcite from shell fragments makes up bulk of chip from core; grains are subangular to apparently subrounded; poorly sorted; well indurated with calcite cement; some in crystalline form indicating fractures; predominantly clear to frosted quartz with scattered oval, subrounded, black lith fragments; trace fine grained moderately well sorted sandstone clast with bright sea-green grains; patchy bright yellow oil and orange calcite mineral fluorescence; fast streaming bright yellow-white to green-white cut fluorescence; bright yellow residual cut fluorescence; pale straw visible cut; spotty stain; weak odor.

9676' SANDSTONE - light yellowish gray, common pink stain from mud thinner; medium to very coarse; subangular to subrounded; poor to occasionally fair sphericity; poorly sorted; well indurated; abundant calcite cement from shell fragments; rare visible outline of microgastropod; very poor apparent porosity; common clear to slightly milky quartz with common dark gray-black subrounded to rounded lith fragments; decreasing calcite from above; patchy sample fluorescence as above; increased intensity of cut fluorescence; straw visible cut; spotty stain; weak odor.

9678.5' SANDSTONE - light gray, salt and pepper; fine to medium with occasional coarse; subangular to subrounded; poor to occasionally fair sphericity; moderately sorted; well indurated with trace friable pockets; calcite cement with hint of bivalve fragments; poor apparent porosity; common clear quartz with scattered soft milky feldspar; scattered gray-black lith fragments; subvitreous with cherty appearance but much softer than chert; patchy calcite fracture fill; decreased oil fluorescence; spotty bright yellow; abundant orange calcite mineral fluorescence; weak yellow cut fluorescence; weak orange-yellow residual cut fluorescence; no visible cut.

9681.7' SANDSTONE - yellowish gray; fine to medium; subangular to subrounded; poor sphericity; moderately well sorted; friable to moderately indurated; grain packed; slightly calcareous; poor apparent porosity but slightly improved over last sample; quartz with spotty feldspar; decreased black lith fragments; trace blue-green grains; trace visible oil on surface of chip after acid has dried; even bright yellow oil fluorescence and light brown oil stain; instant, strong yellow-white to green-white cut fluorescence, turning blue-white over time; opaque bright yellow residual cut fluorescence; straw visible cut; light brown dry ring; light to medium brown oil bleeding from core after 1 - 2 hours; strong light oil odor from core.

9685.4' SANDSTONE - light gray; medium to coarse; subangular; poor to moderate sphericity; moderately sorted; well indurated; grain packed; spotty calcite cement; poor apparent porosity; clear to milky and gray quartz and feldspar; minor black lith fragments; no visible bedding lineation from core chip; oil shows as above.

9688' SANDSTONE - as above becoming slightly finer grained; oil shows as above.

9690.8' SANDSTONE - light gray; fine to medium, predominantly medium; subangular; poor to moderate sphericity; moderately well sorted; moderately well to well indurated; grain packed; spotty calcareous cement; poor apparent porosity but trace minor outgassing when immersed in water; predominantly quartz; minor spotty dark gray grains; oil shows as above.

9693' SANDSTONE - as above.

9698.5' MUDSTONE - (possibly shale); very dark, dusky yellowish brown; hard; tough; dull luster; silty texture; no bedding lineation or fissility in core chip; very slow initial effervescence in HCl; becomes moderately strong and leaves a discolored (bleached) area where applied; no sample fluorescence or visible stain; weakly streaming yellow cut fluorescence; weak yellow residual cut fluorescence; no visible cut; weak petroleum odor.

SHELL CALIFORNIA PRODUCTION, INC.

PDET #43-27

FORMATION SUMMARY

The interval from 57' to 1,020' consists predominantly of silty claystone, sandstone and siltstone. Lost circulation was encountered in the poorly sorted sands of the Tulare Formation at 176' and was not regained until a cement plug was set at 343'. No hydrocarbon shows were encountered and in the upper 80% of the interval only traces of methane gas were observed. The siltstones in the lower portion of this interval appear lithologically gradational to the underlying diatomite section. Cuttings gas readings indicate a distinct break at 1020'.

1020' - 1715'

The diatomite section from 1020' to 1715' is not as well developed as similar sections in South Belridge. Cuttings exhibit a high amount of detrital material and grade from silty diatomaceous clays through silty diatoms to siltstone with intermittent calcareous, and locally glauconitic, sands. Although cuttings gas readings indicate increased porosities through this section and ditch gas (methane only) ranged from 20 to 70 units, no oil indicators were observed.

As in the overlying unit, the lower portion of the diatomite section appears lithologically gradational to the underlying, increasingly detrital, section. Thirteen and three eighths inch casing is set at 1715', a convenient point to break up the section.

1715' - 2800'

Although diatoms and lithologies of diatomaceous origin are present from the Belridge Diatomite down through the older, Antelope Shale, the interval from 1715' to 2800' represents a period of increased detrital influx. The interval consists predominantly of gray-green clay and olive colored shaly mudstones with scattered thin interbeds of marl/limestone. The mudstone is commonly diatomaceous and infrequently grades to clayey diatomite.

Minor traces of reddish-brown oil stain occur in silty/sandy cuttings from 1800' to 1865' and also in diatomaceous mudstones from 1945' to 2040', giving fast, weak, milky-yellow cut fluorescence with traces of weakly iridescent oil sheen. Cuttings gas readings were nil. Ditch gas consisted of methane only. Averaging 10 units to 2270', ditch gas readings increased to an average of 50 units with peaks over 90 units, gradually reducing to an average of 25 units. Overall, the interval shows no real hydrocarbon potential.

2800' - 3300'

Increased induration and slightly improved bedding lineation in ditch samples from 2800' mark the top of the Reef Ridge. The poorly fissile dull olive to brown gray shales that predominate this interval become less diatomaceous in appearance, grading toward more compact brittle mudstones with increasingly more common porcelaneous characteristics. Calcareous microfossils and thin laminations occur in the lower portion of the Reef Ridge. A subtle color change from predominantly olive and brownish grays to increasingly brown and the phosphatic nature of the shales marks the gradational boundary between the Reef Ridge and the underlying Antelope Shale.

Methane and minor amounts of ethane were recorded from the ditch gas throughout the Reef Ridge. In two separate intervals within this section, propane and butane were also observed when ditch gas exceeded 50 units. No oil fluorescence or cuts were observed in the cuttings.

3300' - 4820'

The Antelope Shale in this well can be broken into five members as follows: upper shale (3300' to 3765'); upper siliceous (3765' to 3960'); middle shale (3960' to 4045'); lower siliceous (4045' to 4340'); lower shale (4340' to 4820').

The upper shale is gray-brown becoming medium to dark brown near the top of the upper siliceous member. The cuttings are silty textured, calcareous and weakly to moderately phosphatic. No oil indicators were observed.

The upper siliceous member consists of pale gray-brown to brown porcelanite and porcelaneous shales interbedded with brown silty mudstones (shaly). The porcelaneous cuttings are brittle with a waxy to resinous luster when wet and commonly exhibit translucent edges. The middle shale member is dark chocolate brown with a grainy, earthy appearance. No oil indicators were present.

The lower siliceous member of the Antelope is better developed and more expansive than the upper siliceous zone. The porcelanite and porcelaneous shales which dominate this member are occasionally cherty and exhibit better developed fracturing, a feature not well developed in the upper zone.

Although fractured porcelanites generally exhibit good reservoir qualities, no oil indicators were present in the siliceous members of the Antelope Shale.

The lower member of the Antelope consists of dark brown, poorly fissile, organic rich shales and mudstones. Tan to occasionally dark brown interbeds of limestone and infrequently dolostone, are common. The shale/mudstone cuttings exhibit a grainy texture and are non to slightly calcareous. Unlike the upper portion of the Antelope the lower shale contains very weak oil shows. Traces of black oil stain were observed in limestone/dolostone cuttings. The shale cuttings exhibited no stain or sample fluorescence but occasionally gave very slow, very diffuse, pale greenish cut fluorescence and almost persistent very pale greenish residual cut fluorescence. No oil sheen or petroleum odor was present.

Ethane and propane occurred as minor amounts of the ditch gas at the top of the upper siliceous zone and persisted through the Antelope and underlying McDonald shale. Minor amounts of butane were also detected below 4625'.

The shales of the lower Antelope become very limey to dolomitic as they grade into the underlying McDonald shale. The first loggable amounts of waxy smectite probably represent the best lithologic marker for the Antelope-McDonald boundary.

4820' - 5660'

The shales and mudstones of the McDonald from approximately 4820' to 5660' commonly contain thin interbeds of limestone and occasionally dolostone.

The shales, grading downward from the overlying Antelope shale are very dark brown, moderately to well indurated, silty and noncalcareous to occasionally very slightly dolomitic. Fissility, when discernible is very poor with most cuttings grading to mudstone. The shale/mudstone cuttings become lighter in color and exhibit a more silty, detrital appearance with depth. The most distinctive feature of the McDonald is the numerous interbeds of pale yellow-brown to cream colored limestone whose cuttings exhibit a resinous to sparkling luster with a microsucrosic texture. The limestone cuttings are occasionally dolomitic, especially in the upper section of the McDonald.

Thin interbeds of very fine white to yellow-brown sandstone occur in the McDOnald below 5350'. These sands appear as minor traces in the ditch samples and as a small percentage in samples taken from the desilter.

Very weak traces of oil occur almost persistently in the shales, and occasionally in the limestone and sandstone. The shales exhibit very pale yellow sample fluorescence and give very weak transparent greenish tinted cut fluorescence with repeated attempts.

On occasions the limestones also give extremely weak greenish cut fluorescence and in rare instances exhibit traces of oil stain in microvugs. The sandstone, although not stained, gave occasional pale greenish cut fluorescence with repeated attempts.

The ditch gas consisted of methane with small amounts of ethane through butane. 5660' - 6170' The Miocene Temblor Formation is bounded by the McDonald shale above and the Media silts below. It consists of five distinct sand bodies separated by shaly intervals, except for the fourth and fifth sands, which are separated by an argillaceous layer not easily recognized by drilled cuttings or drill rate. Furthermore, the third sand is apparently truncated by a small normal fault. These five sands occur from 5660' to 6005'. Two lower sands, one of which is locally known as the button bed, are included in this discussion of the Temblor, although they are not normally assigned to this formation.

These light gray sandstones are generally hard, as evidenced by core samples, and consist of very fine to medium grained quartz sand with very common feldspar and lithic grains. Sandstones range from permeable and kaolinitic to tight and calcareous. Gray to brown, silty shales divide the sands. These are firm to hard, non to slightly calcareous, locally micromicaceous or pyritic, and occasionally fossiliferous.

The Temblor sands are probably depleted of oil in this fault block. Ditch gas remained below 30 units (mud weight 9.3) with only traces of petroleum vapors. Lost circulation was a problem in the lower fourth/upper fifth sands. Only traces of oil fluorescence could be found in sandstone cuttings, with heavy, sticky oil coating rare shale cuttings. Cores #2 and #3 had a small amount of oil with yellow fluorescence streaked through more permeable, noncalcareous sandstone layers.

6170' - 6715'

The interval from 6170' to 6715' separating the Temblor and upper carneros sandstones consists of siltstone, very poorly fissile silty shale with intermittent limestone and occasional sandstone interbeds. The siltstones and shales appear as gray to gray-brown, moderately well indurated cuttings with a grainy to gritty texture. Some cuttings exhibit poorly developed fissility and infrequent faint laminations.

The intermittently occurring light yellow-brown limestone cuttings are more numerous in the upper portion of this silty interval, especially from 6200' to 6250'. The cuttings are hard with a resinous to sparkling luster and occasionally grade to calcarenite.

The sandstone is white to brownish gray where silty. Grain size ranges from very fine to medium, being predominantly very fine to fine and grading from friable to moderately well indurated.

Drill rates indicate only one small distinct sand body from 6300' - 6311'. Thin laminations and lenses of fine sandstone grading to siltstone occur in the lower portion of this interval. Sporbo is locally common in fine sandstones at 6450'.

Weak traces of oil occur intermittently in the sandstones and limestones which exhibit very slow, diffuse (infrequently streaming) very pale yellow to greenish cut fluorescence. Traces of dry flaky oil stain occur in very fine sandstone from 6650' to 6690'.

Ditch gas remained below 30 units averaging approximately 10 units. Minor amounts of ethane and propane were recorded throughout the entire section. Butane was first observed from 6547' and persisted through this section into the underlying Carneros sandstone.

6715' - 6853'

The sands of the Upper Carneros are light gray to white, fine to medium grained and distinctively kaolinitic. The increased grain size of the Carneros is reflected in the increased drill rate from 6715' to 6853'. Sporbo and pyrite nuggets are locally abundant. Only extremely weak traces of oil were present in cuttings. Spotty faint to bright white-yellow mineral fluorescence was observed in most samples. Occasional very pale greenish yellow cut fluorescence was obtained with repeated attempts.

Ditch gas ranged from 5 to 25 units and consisted predominantly of methane with minor amounts of ethane and propane. Minor amounts of butane were observed in the upper portion of the Upper Carneros but quickly dropped out.

6853' - 7210'

The interval from 6853' to 7210' separating the Upper and Lower Carneros Sandstone consists of medium to very dark brown moderately to well indurated poorly fissile silty shale (Upper Santos Shale?) Minor sandstone interbeds occur sporadically.

Weak traces of oil persisted throughout most of the interval, generally in the form of very weak yellow residual cut fluorescence. Infrequent traces of medium brown oil stain gave fast, diffuse pale to milky yellow cut fluorescence with pale straw visible cuts and very faint yellow residual cut fluorescence.

Butane was again observed as a component of the ditch gas at the top of this shale interval after having dropped out in the upper portion of the Upper Carneros Sandstone. Ditch gas averaged 20 units, peaking to 90 units at 6984' where pentane gas was recorded in the ditch gas for the first time in this well.

Tight hole problems in the lower portion of this shale continued into the Lower Carneros. The mud weight was raised from 9.2 lbs./gal. to 9.5 lbs./gal. while still drilling through the shale.

7210' - 7735'

The Lower Carneros sandstone is white to light gray, fine to coarse grained, and poorly to moderately sorted. Grains become generally more angular deeper into the formation. Cuttings are moderately to well indurated with spotty calcareous cement. As in the Upper Carneros the sandstones of the Lower Carneros are distinctly kaolinitic with common to abundant white feldspar grains. Minor constituents include lith fragments (predominantly shale), mica, pyrite and bright blue-green grains, possibly glauconite. Apparent porosity was generally poor.

Sloughing shales and intervals of poor returns coupled with tight hole persisted through most of the drilling of the Lower Carneros. A mud weight of 10 lbs./gas. and the last resort addition of the asphaltic chemical X-Pel-G did not solve the problem. Twelve and a quarter inch hole was drilled to a depth of 7576' where the additional problem of lost circulation made it necessary to run 9 5/8" casing which was set at 7057' instead of T.D. because of hole problems. A mud weight of 12.6 lbs./gal. was necessary to stop shale problems and continue drilling 8 1/2" hole.

Weak traces of oil were observed, almost consistently, in the upper 160' of the Lower Carneros. Cuttings with spotty, moderately bright white-yellow mineral/sample fluorescence gave very slow diffuse to occasionally wispy streaming pale yellow cut fluorescence with no visible cuts and faint yellow residual cuts. No oil staining or petroleum odor were observed.

At 7676' - 7680' the sandstone was observed to have bright yellow fluorescent pops with a weak petroleum odor and bright yellow mineral/sample fluorescence. Pentane was recorded in the ditch gas from this interval.

Overall, the ditch gas contained methane through propane with intermittent butane.

7735' - 8040'

The interval from 7735' to 8040' consists predominantly of medium to dark brown moderately to well indurated silty shale with intermittent sandstone beds. No oil attributes were observed although butane was recorded from the ditch gas throughout the interval. Abundant sporbo and increased sand at the very bottom of the interval mark the contact with the underlying Agua sandstone.

8040' - 8175'

Abundant sporbo and glauconite, gray clay, and an increase in sand near the base of the Lower Carneros herald the appearance of the Agua Sand at 8040'. This sand is approximately 108' thick and rests upon shale at 8148'. Apparently depleted and permeable, lost circulation was a persistent problem throughout. Abundant lost circulation material in the mud system made lithologic evaluation difficult.

This light gray sandstone is predominantly fine to medium grained quartz with an occasional coarse component, arkosic and commonly kaolinitic with traces of mica, pyrite, and glauconite. Occasional hard, calcareous streaks caused drilling bones. This sand becomes increasingly silty and argillaceous with depth. Samples of cuttings had a good percentage of dark brown, firm to hard, silty and slightly calcareous shale which was probably slough in large part.

The upper Agua contains some gas - 100 units with a fair amount of petroleum vapors was recorded at 8070' (mud weight 11.3) - but no oil was found in either cuttings or drilling mud. Traces of greenish sample fluorescence became evident below 8090'. Cuts were very weak and no other oil attributes were present.

The Agua here is somewhat thinner than it is on correlation logs and rests on dark brown, hard shale with evidence of polished slickensided surfaces. There is also an increase in ditch gas that one might expect in a fault zone. The formation directly below this shale is probably the Belridge 64 zone. This suggests that a normal fault has placed the 64 zone beneath the Agua sand, faulting out the Bloemer sand and much of the Salt Creek shale.

8175' - 8390'

The "first" Belridge 64 zone (it is repeated at 8810') exists from approximately 8175' to 8390'. The mudlog does not adequately represent this sandstone because of extremely abundant lost circulation material, partial returns, abundant shale slough, and a very slow drill rate, all suggesting a section which is predominantly shale.

Very fine to medium, angular to subangular, light gray quartz sandstone comprises this formation. It ranges from calcareous, very hard and tight to moderately kaolinitic, less indurated, more permeable and porous sandstones. These differences are reflected by drill rate. Accessory minerals include mafics and lithics, feldspar, and occasionally common glauconite. The hard, dark brown shales are largely slough.

Circulation was lost near the top of the "first" 64 zone, and full returns were not regained until approximately 8250'. From 8170' to 8245' only a very slight trace of light oil was seen in the few sandstone cuttings available. Ditch gas remained below 40 units (mud weight 11.3) and cuttings gas did not exceed 12 units. At 8145' oil became visible on shale, pentane became fairly consistent in the ditch gas, and cuttings gas increased slightly. This shale is commonly polished and slickensided, with common calcite fracture coatings. The sandstone cuttings began to increase in amounts and yellow sample fluorescence with weak green-yellow cuts. We also regained full returns. More permeable, less indurated sands below 8293' contain a fair amount of light oil with bright yellow-white fluorescence. Oil decreases at the base of the 64 zone as the sandstone becomes more argillaceous.

This 64 zone is approximately 150' thinner than the repeat at 8815'. The sudden occurrence of pentanes and visible oil, gouged shales, return of full circulation, and a steady increase in flowline temperature indicate a possible normal fault near 8250'.

8390' - 8694'

The interval underlying the Belridge 64 zone from approximately 8390' to 8694' consist predominantly of dark brown moderately to well indurated, calcareous, silty, poorly fissile shales and mudstone with intermittent light gray fine to coarse grained poorly sorted sandstone. The sandy interval from 8428' to 8445' may be the Gibson sand. Glauconite and sporbo are locally abundant from 8650' to 8660'. Persistent weak traces of oil were observed from the shales and mudstones. The sandstones occasionally exhibited spotty dull yellow-orange sample fluorescence and gave slow streaming weak yellowish green cut fluorescence.

Ditch gas ranged from 10 to 90 units and consisted of methane through butane with pentane occurring only at high gas peaks.

Lost circulation was encountered at 8662' with 11.3 lbs./gal. mud weight. The contact with the underlying Bloemer sandstone at 8694' appears sharp.

8694' - 8765'

The Bloemer sandstone is a distinctive body marked by abundant shell fragments and calcite in the top portion of the sandstone. The sandstone is light gray, to light gray-brown, fine to coarse grained, poorly to moderately sorted and slightly friable to well indurated. Core samples exhibited patchy yellow sample fluorescence and occasional strong greenish yellow cut fluorescence with pale straw visible cuts.

Cuts were much weaker from ditch samples. A trace of pinpoint iridescent pops were observed in unwashed samples above the core.

Ditch gas ranged from 40 to 100 units and consisted of methane through pentane. Lost circulation was encountered at 8471' and lost circulation material added to the mud system made sample determination difficult.

8815' - 9165'

A small, apparently shaly section separates the Bloemer sandstone from the underlying, apparently repeated Belridge 64 zone.

The sandstone of the 64 zone is white to light gray, very fine to coarse grained, angular to subangular, poorly sorted, friable to well indurated, and consists of quartz with common to locally abundant feldspar and spotty lithics. Apparent porosity ranged from fair to good in the upper 100' and then decreased, becoming increasingly tight with depth. Thin beds and streaks of brown argillaceous sandstone and sandy shale occur with increased frequency below 9100' where traces of siltstone clasts were observed.

Sample fluorescence exhibited by ditch cuttings was generally an even moderately bright white-yellow to occasionally greenish yellow, white intensity greatly diminished as the cuttings dried, indicating light oil. Cut fluorescence was not as impressive as sample fluorescence and unlike the latter, decreased with depth. The better cuts observed were instantly diffuse pale yellow with slow wispy streamers, becoming greenish yellow. Crushing the cuttings being examined increased the intensity of the cut fluorescence. Crush cuts diminished below 9050' and were not generally fruitful below 9100'. Residual cuts indicate light oil with moderately bright white-yellow to greenish fluorescence. A moderately strong petroleum odor and abundant bright yellow fluorescent oil pops were observed in the upper 50' feet of the 64 zone. Live oil was observed in a small core taken at 8829'.

Ditch gas ranged from 14 to 120 units and consisted of methane through pentane. Although cuts diminished with depth, pentane gas became more consistent in the lower half of the 64 zone. Overall, the interval from 8820' to 9070' appears to be the best bet for a production test.

9225' - 9277'

The poorly developed sandy interval from 9225' to 9277' may represent the, possibly repeated, Gibson sand which lies stratigraphically below the Belridge 64 zone. This sand yielded spotty yellow sample fluorescence with very weak cuts.

9277' - 9470'

The interval from 9277' to 9470' consists of medium to dark brown and gray-brown, well indurated, noncalcareous, poorly fissile shale that grades to mudstone. Traces of sandstone occurred from 9335' to 9405'. Weak greenish yellow cuts were obtained from both the shale and sandstone.

Eight and one half inch hole was drilled to 9450'. Seven inch liner was set to combat lost circulation and running shale apparently caused by geo-pressures (the big fault?) The liner was set at 9403' and it was necessary to raise the mud weight to 16.5 lbs./gal. to solve the shale problem and resume drilling a 6 1/8" hole.

9470' - 9649'

Below 9470' a dramatic change occurs in the shales and mudstones. The medium to dark brown cuttings become soft to firm, crumbly and very calcareous. The cuttings do not appear as pressured as those in the interval above.

Extremely weak traces of oil are exhibited by extremely slow diffuse pale yellow to greenish cut fluorescence from the shales and trace sandstones that occur in this interval.

Ditch gas, suppressed by 16. to 16.5 mud weight ranged from 4 to 22 units, averaging 5 units. Methane, ethane and propane comprised the major percentage of the ditch gas. Butane was observed only intermittently.

The contact with the underlying Oceanic sandstone (?) is fairly abrupt, marked by a two-fold increase in drill rate.

9649' - 9695'

The Oceanic sandstone (?) is light gray to brownish gray (oil stained), fine to medium grained, angular to subrounded, moderately well indurated and locally (9674' - 9678') very calcareous with numerous shell fragments. Although apparent porosity was poor cuttings and core samples exhibited light brown oil staining and even bright yellow sample fluorescence. Cuts obtained were instant bright greenish yellow with straw visible cuts. Good petroleum odor was observed from 9674'.

Oil was observed slowly bleeding from the core, but only after an hour of setting at normal atmospheric pressure. The color of the sample and cut fluorescence indicates a heavier oil for the Oceanic than in the 64 zone but still relatively light (approximately 18 to 20 degrees API).

9695' - 9807'

The interval from 9695' to 9807' consists of medium to dark gray-brown and brown, moderately indurated, intermittently calcareous shale with minor but common amounts of dark green glauconite. Phosphatic material also occurs as a minor visible component. The samples gave off an acrid tarry odor with fair greenish yellow cut fluorescence. No visible staining was observed.

The ditch gas averaged 12 units and consisted of methane through butane with occasional traces of pentane. Production from this interval is very doubtful but it is interesting to see increasing oil attributes in deep shales.

Drilling ceased when the drill string became differentially stuck at a measured depth of 9807.

SHELL CALIFORNIA PRODUCTION, INC.

PDET #43-27

SUPPLEMENTARY DATA LOG

2640' CLAY - dark green-gray; soft; slightly thick, pasty consistency; moderate to increasingly poor solubility; very smooth, creamy texture; slightly silty; sticky; no oil or cut fluorescence.

2670' SHALE - medium gray to slightly brown-gray; firm to slightly hard; occasionally punky; moderate induration; small to medium, subangular to subrounded, tabular cuttings; slightly sparkling to waxy luster; very fine abrasive to smooth texture; becoming slightly diatomaceous in places; slightly improved fissility; predominantly silty; minor trace impure silty limestone; no oil or cut fluorescence.

2700' CLAY - medium to dark green-gray to slightly brown-gray; soft; thick, pasty consistency; moderate to poor solubility; very smooth texture; creamy; slightly silty; creamy; greasy; nonnodular; no oil or cut fluorescence.

2730' SHALE - medium green-gray to predominantly brown-gray; firm; moderate induration; common slightly punky cuttings; small to medium, subangular to subrounded, tabular cuttings; increasingly sparkling to slightly resinous luster; very gritty texture; increasingly diatomaceous; slight increase in apparent porosity; noncalcareous; increased silty limestone; no oil or cut fluorescence.

2780' SHALE - olive green to greenish brown; moderate induration (firm); crumbly; tabular with slightly rounded edges; dull slightly waxy luster; smooth to infrequently gritty texture; poor fissility; commonly flakes when broken; noncalcareous; no cut or sample fluorescence.

2790' SHALE - olive green, occasionally gray-brown; soft to firm, predominantly crumbly; infrequently slightly brittle; tabular, slightly rounded; dull to slightly waxy luster; grainy, slightly abrasive texture; infrequently slightly translucent along very thin edges; very poor fissility; commonly flakes; extremely slight very slow pinpoint effervescence from HCl; no sample or cut fluorescence.

2810' SHALE - olive gray, green-gray-brown; moderately indurated, increased firmness; crumbly to increasingly brittle, occasionally breaking with snap; tabular with slight increase in sharpness; still predominantly slightly rounded edges; dull to slightly waxy luster; silty, abrasive texture; improved bedding lineation with some flaky cleavage; poor fissility; slightly calcareous from pinpoint areas; more brownish cuttings slightly porcelaneous; no sample or cut fluorescence.

2835' SHALE - as above; some mottling and streaks of white; soft calcilutite, shale becoming increasingly gray-brown; scattered porcelaneous mudstone with extremely faint microlaminations; limestone is white, greenish gray; soft to firm; tabular to irregularly shaped cuttings; gritty grainy texture, almost sandy in lighter cuttings; dirty impure gradings to calcilutite; no cut fluorescence.

2850' SHALE - medium olive green, gray, green-brown; moderate to occasionally well indurated; crumbly to tough, occasionally slightly brittle; compact tabular cuttings; dull, very slight waxy luster; smooth to very finely abrasive texture with a slightly grainy appearance; dents and gouges fairly easily; scattered stair stepped cleavage; poor fissility; no apparent laminations; slightly to moderately calcareous from pinpoint areas; no effervescence in water.

2865' SHALE - olive green, drab green; moderate induration; crumbly; blocky to predominantly tabular with slightly rounded edges; dull to slightly waxy luster; very finely abrasive texture; increased fissility but still poor; slightly calcareous from pinpoint areas; minor scattered microfossils; silty in places; occasionally marbled with pale gray calcilutite; no sample or cut fluorescence.

2900' SHALE - medium gray to slightly brown-gray; slightly soft to firm; moderate to poor induration; small to medium, subangular to rounded, tabular to slightly platy cuttings; sparkling to waxy luster; very gritty texture; punky appearance; very diatomaceous; good, uneven flaky fissility; increase in apparent porosity; no oil or cut fluorescence.

2970 SHALE - greenish brown, gray-brown; moderate induration; tough to brittle; tabular, increasingly angular; dull to slightly resinous; predominantly waxy; faint red laminations in porcelaneous shale, silty in places; slightly calcareous; no sample or cut fluorescence.

3000' SHALE - olive brown-gray; moderate induration, occasionally well; tough to slightly brittle; tabular; dull waxy luster; smooth to very fine abrasive texture; poor fissility; scattered faint laminations; slightly calcareous; scattered white microfossils grading to porcelaneous mudstone; no cut fluorescence.

3030' SHALE - medium gray-brown; moderate to well indurated; tough; blocky to tabular, angular; dull waxy, occasionally resinous luster; grainy to smooth, increasing porcelaneous shale with translucent edges; scattered white microfossils in more detrital cuttings; scattered laminations; slightly calcareous; no cut fluorescence.

3060' SHALE - olive green, gray-brown; moderate induration; predominantly crumbly, occasionally tough; tabular; dull to slightly waxy luster; very finely abrasive to occasionally grainy texture; apparent slight increase in detrital material; slightly improved fissility with common flaky cleavage; scattered white microfossils; very slightly calcareous in places; no sample or cut fluorescence.

3090' SHALE - medium gray-brown; moderately indurated; crumbly to tough; tabular with generally sharp edges; dull to occasionally slightly resinous luster; finely abrasive to gritty texture; commonly silty to grainy appearance; good to fair flaky cleavage; poor fissility; slightly to moderately calcareous from pinpoint areas; occasionally translucent on thin edges.

3120' CLAY - dark gray-green; very soft; thin to slightly thick pasty consistency; excellent solubility; very gritty texture; nonnodular; very silty; no oil or cut fluorescence.

3150' SHALE - light to medium gray-brown; fine to increasingly hard; moderate to well indurated; small to medium, subangular to rounded, tabular to slightly blocky cuttings; slightly resinous to sparkling luster; very rough grainy texture; noncalcareous; very silty; low apparent porosity; minor trace light tan calcareous laminations; weak trace foram ghosts; slight trace phosphatic material; poor to moderately uneven fissility; no oil or cut fluorescence.

3180' CLAY - medium to dark olive green; soft; thin, slightly pasty consistency; good solubility; very gritty texture due to abundant shale fracture; very silty; slightly greasy; poor to moderate cohesion; nonnodular; no oil or cut fluorescence.

3210' SHALE - medium gray to gray-brown; firm; moderately indurated; occasionally soft, slightly punky, diatomaceous cuttings; small to medium, subrounded, tabular cuttings; increasing sparkling luster; very fine abrasive to gritty texture; increasingly micaceous; becoming increasingly calcareous; indistinct trace microfossil debris; infrequent tan calcareous laminations; poor to moderate uneven fragment; no oil or cut fluorescence.

3240' CLAY - medium to very dark olive green to gray-green; soft, slightly thin pasty consistency; very good solubility; very gritty texture; slightly creamy in places; occasionally sticky; nonnodular; silty; no oil or cut fluorescence.

3270' SHALE - medium brown to gray-brown; firm to slightly hard; moderate to well indurated; medium, subangular to subrounded, tabular cuttings; dull to sparkling luster; gritty to very grainy texture; micaceous; very silty; punky occasionally; minor trace thin, tan to cream calcareous laminations; no cut fluorescence.

3300' CLAY - dark olive brown; slightly stiff to predominantly soft; slightly thick pasty consistency; slight decrease in solubility; gritty to slightly smooth texture; slightly creamy; greasy; increasingly sticky; moderate to good cohesion; silty; no cut fluorescence.

3330' SHALE - medium to slightly dark brown and gray-brown; firm to slightly hard; moderate to moderately well indurated; slight increase in overall hardness; very small to medium, subangular to subrounded, tabular to slightly platy cuttings; sparkling to slightly residual luster; slightly smooth to grainy texture; micaceous; calcareous; slight trace porcelanite fragments; no cut fluorescence.

3360' SHALE - medium to increasingly dark brown to gray-brown; firm to slightly hard; moderately well indurated; very small to medium, subangular to subrounded tabular to platy cuttings; sparkling luster; grainy texture; micaceous; slightly porcelanite; predominantly very silty; minor trace soft, punky appearing fragments; no cut fluorescence.

3390' CLAY - dark green-brown to olive green; slightly soft to increasingly stiff; thick, pasty consistency; moderate to good solubility; gritty to abrasive texture; very silty; slightly sticky; greasy; nonnodular; slightly micromicaceous; trace dirty white silty limestone; no cut fluorescence.

3410' SHALE - medium gray-brown; fine to slightly hard; moderate to moderately well indurated; small to medium, subangular to subrounded, tabular to slightly platy cuttings; increasing sparkling luster; very fine abrasive texture; very micromicaceous; persistently calcareous; trace foram remnants; medium to occasionally good fissility; trace limestone; no cut fluorescence.

3430' CLAY - dark green-brown to olive green; slightly soft; thin to slightly thick consistency; good solubility; gritty texture; micaceous; nonnodular; trace limestone; silty; no cut fluorescence.

3480' SHALE - gray-brown; moderately indurated; crumbly, tabular cuttings with flaky cleavage; dull to sparkling luster; silty abrasive texture; poor fissility; slightly moderately calcareous; occasionally slightly translucent on thin edges of limestone; no sample or cut fluorescence.

3510' SHALE - gray-brown; moderately indurated; tough, slightly brittle; dull with slight sparkle to occasionally resinous luster; predominantly rough abrasive texture; gritty appearance; slightly calcareous with scattered microvugs; porcelaneous in part with commonly translucent edges and nondetrital appearance slightly improved fissility; minor limestone; no cut or sample fluorescence.

3540' SHALE - as above; slightly darker; sharp edges gritty abrasive; occasional pods of microfossil; no sample or cut fluorescence.

3570' SHALE - medium gray-brown, becoming browner; moderate induration; crumbly to tough, occasionally slightly brittle; tabular sharp edges; flat to infrequent resinous luster with sucrosic sparkle when dry; gritty abrasive texture; flaky cleavage; common microfossils; in white patches and layers; moderately calcareous; more brittle cuttings; occasionally exhibit translucent edges; occasionally very faint laminations.

3600' SHALE - as above improved fissility but still poor common microfossils; slight increase in porcelaneous claystone; trace very faint orange mineral fluorescence; no sample or cut fluorescence.

3630' SHALE - brown, gray-brown; moderately indurated; slightly moderately brittle; tabular, sharp edges; dull luster; very finely abrasive texture, occasionally gritty fair fissility; scattered microfossil; moderately slightly calcareous; no visible laminations.

3660' SHALE - gray-brown; moderately indurated; slightly brittle; tabular, occasionally platy; dull, slightly resinous luster; abrasive flaky appearance with common uneven cleavage; moderately calcareous; streaks and microfossil; limestone is tan; firm to hard dirty faint laminations; gritty; slightly resinous; no cut.

3690' SHALE - medium gray-brown, brown; moderately indurated; slightly brittle becoming more so; tabular and sharp dull, slightly resinous; very finely abrasive commonly faint microlaminations; slightly transparent on edges; poor fissility uneven cleavage; moderately calcareous; trace mineral Cl; no cut fluorescence.

3750' SHALE - dark to very dark brown and gray-brown; firm to very hard; well indurated; occasionally slightly punky appearing cuttings; small to occasionally large, subangular to subrounded, tabular to slightly blocky cuttings; slightly brittle; strong sparkling luster; rough grainy texture; slightly micaceous; becoming increasingly porcelaneous; occasional translucent edges; slightly splintery to hackly fracture; minor phosphatic inclusions; slightly silty limestone fragments; no cut fluorescence.

3780' PORCELANEOUS SHALE - dark tan to medium brown; very hard; well indurated; small to medium, subangular to angular, tabular to slightly blocky cuttings; slightly resinous to waxy luster; smooth to grainy texture; slight increase in thin microlaminations; slight to pinpoint irregular-like pores formed from dissolution of foram rock.

3810' PORCELANITE - light tan, bone white and cream-brown; very hard; very brittle; very small to medium sharp, angular to subangular, shard-like cuttings; pearly to resinous luster; smooth to slightly grainy texture; common subconchoidal to splintery fracture; no cut fluorescence.

3840' SHALE - tan to brown; very hard; well indurated; small to medium, angular, tabular to blocky cuttings; waxy to sparkling luster; grainy texture; minor pinpoint vugs due to foram dissolution; weak trace laminations; commonly grades to porcelanite; no cut fluorescence.

3870' PORCELANITE - tan, cream, and bone white; very hard; very brittle; small to medium, sharp, angular, slightly blocky shard; slightly pearly luster; smooth to slightly grainy texture; abundant white, slightly calcareous laminations; minor phosphatic staining; no cut fluorescence.

3890' SHALE - medium brown and gray-brown; hard to very hard; well indurated; slightly brittle; small to predominantly medium, subangular, slightly blocky cuttings; slightly sparkling to resinous luster; gritty to grainy texture; predominantly very porcelaneous; trace white calcareous laminations and inclusions; poor, uneven fissility; low apparent porosity; minor trace hairline microfractures; no cut fluorescence.

3910' SHALE - dark brown; well indurated; brittle, crunchy, sharp blocky cuttings; resinous luster; commonly translucent on edges; generally rough uneven texture but not grainy or gritty-hackly fracture; commonly faint grayish microlamination; give an overall translucent appearance to many cuttings; calcareous in places with occasional brown streaks; darker cuttings are more detrital; no sample or cut fluorescence.

3930' PORCELANEOUS SHALE - as above; light to medium gray-brown cuttings; hard; brittle, blocky angular cuttings; resinous luster when wet, matte when dry; smooth cryptocrystalline texture; translucent quartz; microlaminated; slightly calcareous; no sample fluorescence or cut.

LIMESTONE - tan, cream, light gray-brown; hard; block; subresinous; very slightly sucrosic; appears very much like porcelanite but tough and effervescing rapidly and continuously; moderately bright yellow mineral fluorescence; no oil stain; no cut.

3945' PORCELANITE - light gray-brown, tan; firm to hard; can be gouged; brittle, sharp tabular cuttings; resinous luster when wet, slightly resinous to matte when dry; smooth microcrystalline texture although fractures to hackly cuttings; commonly translucent quartz; microlaminated; slightly calcareous in places; grades to porcelaneous shale with slight grainy texture; no sample or cut fluorescence.

3960' SHALE - very dark brown, chocolate brown; hard; tough to moderately brittle; dull earthy to subresinous luster; grainy texture; more brittle siliceous cuttings are hackly and grade to porcelaneous shale; detrital cuttings contain scattered white microfossil.

3975' LIMESTONE - tan, cream; hard; sharp tabular microsucrosic; with slightly resinous luster; greenish-yellow mineral fluorescence; no cut fluorescence; sample has become more clayey, less sharp to the touch, more earthy; porosity increase as seen in cuttings gas.

3975' SHALE - very dark brown, chocolate brown; firm-hard; tough to moderately brittle; tabular, angular, dull to subresinous luster; abrasive grainy texture; distinct increase in detrital content; scattered flaky cleavage; still slightly siliceous; no sample fluorescence or cut.

4005' SHALE - dark chocolate brown; firm to hard; tough to moderately brittle; blocky, tabular; dull to satin luster; becoming more earthy; grainy texture; increase clay content; poor fissility; occasionally flaky cleavage; very slightly calcareous; occasionally cuttings with very faint microlaminations; no sample or cut fluorescence.

4020' SHALE - dark chocolate brown, reddish-brown; firm to hard; crumbly to slightly brittle; tabular; predominantly sharp increase slightly rounded edges; dull luster becoming more earthy; grainy to gritty texture; poor fissility; some flaky cleavage; occasionally faint microlaminations; no visible bugs; very slightly calcareous from pinpoint areas; persistent porcelaneous shale; slough or intermittent interbeds; no sample or cut fluorescence.

4035' SHALE - very dark brown; moderately indurated; slightly brittle; tabular; earthy; grainy; fair fissility; flaky cleavage; occasional claystone; no sample or cut fluorescence.

4050' SHALE - dark brown; firm to hard; tough brittle; tabular; earthy; gritty; grainy; poor fissility; stair stepped to flaky cleavage; grades to claystone; non to slightly calcareous; persistent porcelanite shale; medium brown resinous brittle; no sample or cut fluorescence.

4080' SHALE - medium gray-brown to brown; moderately indurated; hard; brittle; sharp tabular cuttings; resinous luster; smooth to slightly grainy texture; commonly translucent edges; microlaminated; commonly white microfossil ghosts; porcelaneous traces dark brown sucrosic dolostone/limestone; no sample or cut fluorescence.

4110' PORCELANITE SHALE - medium gray-brown, light reddish-brown; firm to hard; brittle; blocky, tabular, angular; resinous; slightly grainy; translucent edges; microlaminated; common styololitic fractures; some dolostone fracture filling.

4130' PORCELANITE - tan, pale gray-brown, light brown; hard; brittle; tabular, sharp, angular; resinous to matte; translucent edges; smooth texture although hackly fracture; common microlaminations; no sample or cut fluorescence.

4155' PORCELANITE - light gray-brown, tan, caramel brown; hard; brittle; tabular, sharp, cherty; resinous luster; smooth texture; hackly fracture with occasionally thin film white dolomite limestone; slightly mottled to microlaminated; occasionally stretching structures visible in laminations; no sample or cut fluorescence.

4170' SHALE - medium brown to gray-brown; very hard; well indurated; small to medium, subangular, blocky to tabular cuttings; strong sparkling luster; gritty to abrasive texture; calcareous; common thin, white laminations; commonly grades to porcelaneous shale; no oil or cut fluorescence.

4200' SHALE - medium to dark brown and gray-brown; very hard; well indurated; brittle; medium, angular to subangular, tabular to blocky cuttings; weak sparkling luster; grainy to abrasive texture; siliceous; commonly grades to porcelaneous shale; infrequently laminated; occasionally sharp contact with porcelanite; common limestone streaks; no oil or cut fluorescence.

4230' PORCELANITE - tan, cream, and medium brown; very hard; very brittle; sharp, angular, slightly blocky to tabular shards; slightly sparkling to resinous luster; smooth to occasional sucrosic texture; commonly laminated; minor distorted foram ghosts; occasionally tan healed hairline microfracture; abundant limestone; splintery to subconchoidal fracture; trace yellow mineral fluorescence attributed to limestone; no oil or cut fluorescence.

4260' LIMESTONE - tan, light brown-yellow, cream and bone white; very hard; small to occasionally large, angular to subangular, blocky cuttings; slightly pearly to strong sparkling luster; very sucrosic texture; cryptocrystalline; occasional cherty lamination; minor microfractures; impure and silty in places; bright to moderately bright yellow mineral fluorescence; no oil or cut fluorescence.

4290' PORCELANEOUS SHALE - tan to medium brown; hard to very hard; becoming slightly crunchy; well indurated; slightly brittle; commonly grades to porcelanite; infrequent grades to slightly argillaceous chert; minor trace disseminated pyrite; poor fissility; porcelanite exhibits light gray and white-tan band; microfractures occasionally contain secondary siliceous mineralization; siliceous overgrowths; occasionally observed on exposed fracture surface; no oil or cut fluorescence.

4320' SHALE - medium to very dark brown and chestnut brown; firm to hard; moderate to well indurated; very crunchy; marked decrease in porcelanite; slight improvement in fissility; very grainy texture; minor lamination; very weakly calcareous in places; generally slightly porcelaneous; slightly micaceous; occasional cuttings have a phyllitic luster; general splintery fracture; minor trace tan healed microfractures; no oil or cut fluorescence.

4350' SHALE - medium to very dark brown; firm to slightly hard; moderate to well indurated; crunchy; slightly brittle; small to medium subangular, tabular to slightly blocky cuttings; slightly sparkling luster; very rough grainy texture; slightly silty; decrease porcelaneous; weakly calcareous in places; predominantly silty; minor light tan and dark brown lamination; minor streaks bone white microcrystalline limestone; no oil or cut fluorescence.

4370' CLAY - medium to dark brown and slightly greenish-brown; soft; thick, pasty consistency; moderate to good solubility; very silty; slightly sticky; very gritty texture; no oil or cut fluorescence.

4395' SHALE - medium dark chestnut brown; firm to hard; tough to brittle; tabular to occasionally blocky; earthy to slightly satin luster; grainy to silty appearance; poor fissility scattered cuttings exhibit microlaminations; commonly mottled appearance; lighter cuttings commonly grade to mudstone; slightly calcareous in places; scattered drab green siltstone with smectite matrix; no sample or cut fluorescence.

4410' SHALE - as above; medium dark brown grading to light brown claystone; blocky tabular; abrasive; dull earthy luster; gritty silty luster; non to very slightly calcareous with occasional visible microfossil; poor fissility; occasionally faint microlaminations; noncalcareous; trace scattered dark brown tarry oil stain; fast streaming light yellow cut fluorescence; faint yellow residual straw visible.

4410' LIMESTONE - cream, tan; very hard; blocky, angular; slightly resinous to sucrosic luster; smooth to sucrosic texture; microcrystalline; dolomitic in part; no visible oil straw.

4425' SHALE - dark gray-brown to medium reddish-brown; moderately indurated; crumbly to brittle; tabular to blocky earthy to subresinous luster; grainy slightly abrasive texture; commonly tan to white microlaminations more distinct when dry; chestnut brown cuttings porcelaneous in part; predominantly high detrital occasionally grades to and interbedded with moderately expansive claystone; scattered dull greenish-gray clay/siltstone; no sample fluorescence.

4440' SHALE - medium chestnut brown; firm to hard; crumbly to very tough; tabular to blocky; dull earthy to satin luster; grainy texture; fair to good bedding lineation; poor fissility; small stair stepped cleavage; very slightly calcareous in places; rare visible microfossil; minor microlaminations.

4470' SHALE - dark gray-brown, chestnut brown; firm to slightly hard; tough to crumbly tabular occasionally slightly rounded; dull earthy luster; grainy texture; occasionally poor fissility in firmer cuttings; increase apparent clay component; more soluble; predominantly noncalcareous; no sample or cut fluorescence; very weak yellow residual cut fluorescence.

4500' SHALE - medium to dark brown, bray-brown; firm to slightly hard; crumbly to brittle; tabular increasingly rounded; dull earthy to slightly satin luster; grainy slightly gritty; poor fissility, more brittle cuttings flaky; non to very slightly calcareous; occasional tan calcareous laminations; silty in places; no sample or cut fluorescence.

4530' SHALE - dark gray-brown, chestnut brown; soft to slightly hard; tabular; rich earthy luster with slight sparkle when dry; clayey; grainy texture; poor fissility; infrequent microlaminations; grades to claystone; diatomaceous appearance but density is higher; no sample or cut fluorescence; trace green-yellow residual cut fluorescence.

4540' SHALE - as above; trace blocky, silty cuttings with white phosphatic blotches or stains possible vug filling.

4540' CLAYSTONE - medium brown; soft to firm; crumbly; blocky to rounded cuttings; dull earthy luster; moderately expansive; now malleable; noncalcareous; silty; no cut fluorescence.

4550' SHALE/MUDSTONE - medium to very dark brown; soft; slightly hard; crumbly; tabular to blocky with rounded edge; earthy; grainy occasionally silty appearance; trace cleavage; no laminations; non calcareous.

4560' SHALE - black-brown; firm to hard; crumbly; tough; punky; clayey; massive; no laminations; some fissility.

4570' SHALE/MUDSTONE - as above; slightly firmer; dark brown microsucrosic lamination; tabular; blocky; subresinous oil stain.

4640' CLAY - dark, rich brown; soft to becoming slightly stiff; very thick pasty consistency; moderate to good solubility; gritty texture; slightly sticky; very silty; nonnodular; pale yellow on background sample fluorescence; slow, diffuse yellow-green cut fluorescence following repeated cuts; pale yellow residual cut fluorescence.

4650' SHALE - rich dark brown to gray-brown; firm to slightly hard; moderate to well indurated; slightly brittle; predominantly very crunchy; has slight diatomaceous surface appearance; strong sparkling luster; abrasive to gritty texture; poor apparent porosity; moderate, uneven fissility; very micromicaceous; silty; common limey dolostone fragments; oil as above.

4660' DOLOSTONE - caramel brown; very hard; brittle; sharp, angular, blocky cuttings; strong sparkling luster; highly sucrosic texture; slightly hackly fracture; minor white to cream calcareous inclusions which may be foram remnants; very limey; dense; oil as above.

4670' SHALE - dark chocolate brown to caramel brown; firm to hard; increasingly occasion of softer, punky, crunchy cuttings with diatomaceous surface appearance; small to medium, subangular to subrounded, tabular cuttings; strong sparkling to slightly resinous luster; very gritty to grainy texture; very micaceous; very silty; moderately uneven fissility; softer cuttings exhibit slight increase apparent porosity; oil as above.

4680' CLAY - dark brown to slightly greenish-brown; soft; thick, pasty consistency; moderate to good solubility; slightly punky, weak diatomaceous feel; sticky; nonnodular; very silty; oil as above.

4690' SHALE - medium chestnut brown; slightly firm to increasingly hard; generally well indurated; persistent chunky fragments; small to medium, subangular to rounded, tabular cuttings; sparkling to resinous luster; very grainy to finely abrasive texture; very micaceous; slightly porcelaneous in places; weak trace very fine laminations; slightly pitted surface apparently; oil as above.

4700' DOLOSTONE - tan to medium brown; very hard; brittle; medium, subangular, slightly blocky cuttings; slightly pearly to predominantly sparkling luster; slightly smooth to sucrosic texture; limey; weakly hackly fracture; minor white, strongly calcareous inclusions; minor trace hairline microfractions; oil as above.

4710' SHALE - medium brown to increasingly dark brown to black-brown; becoming increasingly hard and brittle; well indurated; medium to occasionally large, subangular to subrounded, tabular cuttings; sparkling luster; abrasive to gritty texture; micaceous; very weakly dolostone to predominantly silty; moderate, uneven fissility; poor apparent porosity; very pale yellow to orange background sample fluorescence; slow, diffuse green to yellow-green cut fluorescence following repeated cuts.

4720' LIMESTONE - tan, cream and bone white; very hard; sharp, angular to subangular, brittle cuttings; slightly waxy to pearly luster; sparkling to sucrosic luster; dolomitic, slightly hackly fracture; minor hairline microfractures; microcrystalline; predominantly pure to occasionally silty; very weak yellow mineral fluorescence; oil fluorescence as above.

4730' SHALE - very dark brown to black-brown; slightly firm to predominantly hard to very hard; well indurated; very small to medium, subangular to subrounded, tabular to slightly tabular cuttings; sparkling to resinous luster; very fine abrasive texture; micaceous; poor to moderate apparent porosity; siliceous to slightly calcareous; common limestone fragments; oil as above.

4740' LIMESTONE - tan, cream and predominantly bone white; very hard; dense; microcrystalline; trace microfractures and very thin laminations; slightly hackly fracture; occasional pyritized foram remnants; weak yellow mineral fluorescence; oil as above.

4750' CLAY - dark brown to greenish-brown; very thin, slightly pasty to liquid consistency; good solubility; very gritty texture; minor soft, malleable nodules; very silty; slightly punky at times; shale exhibits oil indicators similar to previous sample; no oil sheen or live oil pops.

4760' SHALE - dark brown to black-brown to dark tan; slightly firm to predominantly hard; well indurated; sparkling luster; gritty to abrasive texture; micaceous; trace pyritized forams; weak trace laminations; becoming increasingly limey; oil as above.

4770' CLAY - dark brown; very soft; very thin liquid consistency; very good solubility; gritty texture; poor cohesion; very silty; nonnodular; shale exhibits oil indicator as above.

4780' SHALE - medium to dark brown and dark tan; hard; slightly crunchy; brittle; small to medium, subangular to subrounded, tabular to slightly blocky cuttings; sparkling luster; very gritty texture; becoming increasingly limey to slightly dolomitic; weak trace pyritized forams; poor fissility; harder cuttings exhibit very fine laminations; oil as above.

4790 LIMESTONE - white, tan, and bone white; very hard; slightly brittle; small to medium, sharp, angular cuttings; slightly pearly to resinous luster; slightly smooth to sucrosic texture; microcrystalline; slightly dolomitic; occasionally silty streaks; minor pyritized foram inclusion; increasing pale yellow mineral fluorescence; oil as above.

4800' SHALE - becoming predominantly dark tan to light chestnut brown; very limey; readily reacts to HCl; minor pyritized forams; very gritty; crunchy; increasing occurrence of very fine laminations; oil as above.

4810' SHALE - dark tan to chestnut brown; hard; well indurated; slightly crunchy; poor apparent porosity; common laminations; abundant very fine limestone fragments; strong spotty bright yellow-green mineral fluorescence.

4820' SHALE - medium to dark brown, very dark gray-brown; hard; tough to brittle; hackly sharp-edged tabular cuttings; dark gray cuttings are distinctly detrital with earthy luster and grainy texture; medium brown cuttings are limey to dolomitic with rough mottled appearance; many cuttings are phosphatic with scattered visible remains; scattered faint yellow-brown mineral fluorescence; rare trace extremely slow pale greenish-yellow cut fluorescence; no visible cut; pale green residual cut commonly green and brown smectite.

4830' SMECTITE - bright yellow-green, olive green, dark burnt orange; firm; waxy luster and texture; flakes like old wax when broken; translucent where thin; moderately to extremely bright yellow; occasionally orange mineral fluorescence; very poor porosity; no cut.

4830' SHALE - light to very dark chestnut brown; very dark gray-brown; hard; tough to brittle; sharp, hackly, tabular to blocky cuttings; darker cuttings are predominantly more detrital/silty whereas lighter cuttings are dolomitic; common faint microlaminations.

4840' LIMESTONE - pale yellow-brown, tan, occasionally dark brown; hard; blocky to tabular; resinous to sparkling luster; more pure cuttings are microsucrosic and crystalline; commonly grades to limey shale; dolomitic in part; pale yellow mineral fluorescence; very weak diffuse greenish-yellow cut fluorescence from bulk; no visible cut; no oil stain; some pipe dope after wiper run.

4860' SHALE - medium to dark brown, chestnut brown and dark gray-brown; firm to hard; blocky to tabular, hackly; dark cuttings are softer with earthy luster and grainy texture; light brown and chestnut cuttings are hackly and slightly dolomitic; trace white microfossils in darker cuttings along with minor fissility; scattered fine yellow mineral fluorescence; no initial cut fluorescence; extremely slow diffuse; very pale greenish-yellow cut fluorescence dark shale; no cut from limestone.

4870' SHALE - increased dark brown; firm to hard; crumbly to tough; blocky to tabular; increase earthy luster and grainy texture; very dark cuttings commonly grade to mudstone; minor poor fissility; some subparallel cleavage; no sample fluorescence; extremely slow and weak very pale diffuse greenish-yellow cut fluorescence; no visible cut; very pale green-yellow residual.

4880' SHALE - very dark brown; firm to very hard; blocky to tabular with predominantly sharp edges; becoming more earthy in appearance; dull to slightly satin luster; grainy to silty texture; occasional microlaminations in shard brittle shales; trace white microfossil inclusion in more earthy cuttings; calcareous in places; still common dolomitic shale scattered smectite; no sample fluorescence; very weak cut as above.

4890' LIMESTONE - pale yellow-brown, pale green-gray; hard; block to tabular; resinous to sparkling; microsucrosic; occasional mottling; no laminations or banding; less dolomitic than above; fine and yellow mineral fluorescence; no cut fluorescence; no residual.

4900' SHALE - light brown, chestnut brown; firm to hard; tough to brittle; sharp tabular cuttings; dull earthy to dull satin luster; rough abrasive texture; light cuttings are limey to dolomitic; minor bands and streaks; extremely weak residual.

4910' DOLOSTONE/DOLOSHALE - overall shale becoming more detrital and earthy; light to dark brown; firm to hard; earthy to flat luster; grainy to abrasive; increase clay content; trace pale gray siltstone and some green pyritic siltstone.

4920' SHALE - medium brown; firm to hard; crumbly, tough; tabular with increasing round earthy grainy and very finely abrasive; increase clay grading to mudstone; no apparent laminations.

4930' SHALE - very dark chestnut brown; hard; tough to slightly brittle; block, angular; dull satin luster to earthy nonfissile trace planar cleavage; siliceous to very slightly dolomitic; nonlaminated; very weak greenish cut fluorescence.

4940' SHALE - as above; very dark brown; more earthy and grainy; slightly phosphatic.

4940' LIMESTONE - light brown, tan; hard; blocky; slightly resinous; increasingly mottled and impure grading to limey shale; very finely abrasive to microsucrosic; minor shaly cleavage to stair stepped fracture; pale yellow mineral fluorescence; no cut.

4950' SHALE - very dark brown; firm to slightly hard; crumbly to tough; blocky to tabular with common rounded edges; dull earthy luster; grainy silty appearance; light cuttings grade to medium brown mudstone; non to very poorly fissile; noncalcareous; no laminations; no sample fluorescence or cut.

4960' CLAY - dark brown; thin liquid consistency; very good solubility; very gritty texture; very silty; minor trace gray nodules; slightly calcareous in places; no oil or cut fluorescence.

4970' LIMESTONE - dark tan, gray-tan, and bone white; very hard; medium, angular to subangular, slightly blocky cuttings; slightly pearly luster; slightly sucrosic to abrasive texture; microcrystalline; slightly silty in places; hackly fracture; pale yellow mineral fluorescence; no oil or cut fluorescence.

4980' SHALE - dark brown to gray-brown; hard to very hard; well indurated; medium to increasingly large, subangular to subrounded, tabular to slightly blocky cuttings; sparkling luster; gritty to abrasive texture; very silty; slightly calcareous; micaceous; trace smectite, trace pyrite; very pale yellow; yellow background sample fluorescence; very slow, diffuse, pale green cut fluorescence following repeated cut attempts.

4990' LIMESTONE - tan; gray-tan, bone white; very hard; microcrystalline; sharp, angular to subangular cuttings; pearly luster; sucrosic texture; minor silty laminations; weak trace vuggy porosity; predominantly very dense; trace hairline microfractures; oil as above.

5000' SHALE - dark gray-brown to dark brown; slightly firm to predominantly hard; well indurated; predominantly siliceous; poor fissility; low apparent porosity; weak trace pyrite fragments; minor calcareous inclusions; oil as above.

5010' LIMESTONE - cream, light yellow-brown; hard to very hard; brittle; sharp, angular shards; slightly pearly to waxy luster; slightly smooth to predominantly sucrosic texture; trace microfractions; microcrystalline; pale, spotty fluorescence mineral fluorescence; oil as above.

5020' SHALE - medium to dark gray-brown to brown; firm to hard; marked decrease in hardness; moderate to well indurated; very small to medium, subangular to subrounded, tabular cuttings; resinous to sparkling luster; very grainy texture; slightly crunchy; nodular, uneven fissile; low apparent porosity; minor calcareous inclusions; possibly foram debris; persistent trace pyrite; oil as above.

5030' CLAY - dark brown; slightly stiff to soft; thick pasty consistency; moderate to good solubility; very gritty texture; slightly punky and greasy; very silty; minor small malleable nodules; slightly sticky; no oil sheen or pops; shale exhibits very weak pale yellow-gold fluorescence and slow diffuse green to green-yellow cut fluorescence following repeated cut attempts.

5040' SHALE - dark brown; very hard; well indurated; small to medium, subangular to subrounded cuttings; sparkling luster; gritty texture; trace lamination; very siliceous; minor calcareous inclusions; trace pyrite; oil as above.

5060' CLAY - very dark brown to gray-brown; soft to slightly stiff; increasingly thick, pasty consistency; moderate to good solubility; very gritty texture; slightly sticky; very silty; occasionally slightly punky; minor increase very small, soft, slightly malleable nodules; shale cuttings exhibit pale yellow background sample fluorescence.

5070' LIMESTONE - white bone to white and cream; very hard; very small to medium, sharp, angular shards; slightly pearly to resinous luster; predominantly sucrosic texture; slightly silty interlamination; minor trace vugs; generally very dense; weak trace pale yellow background sample fluorescence; very slow diffuse, pale green to yellow-green cut fluorescence following repeated cut attempts.

5080' SHALE - dark to very dark brown and chestnut brown; slightly firm to hard; moderate to well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling luster; gritty to abrasive texture; slightly calcareous in places; occasionally crunchy; weak trace pale tan laminations; abundant limestone shards; oil as above.

5090' CLAY - dark brown to gray-brown; soft to slightly stiff; slightly thick, pasty consistency; moderate to good solubility; slightly sticky; silty; gritty texture; weak trace nodules; persistent limestone fragments; shale exhibits oil as above.

5100' SHALE - dark to very dark brown and black-brown; hard to very hard; well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling to resinous luster; fine abrasive texture; micromicaceous; more siliceous; slightly hackly fracture; weak trace calcareous inclusions; very pale powdery yellow background fluorescence; slow, diffuse pale green to green-yellow cut fluorescence following repeated cut attempts.

5110' CLAY - very dark brown to gray-brown; increasingly stiff; thick, pasty consistency; moderate solubility; very silty; slightly sticky; gritty texture; slightly nodular; increased cohesion; shale exhibits oil as above.

5120' SHALE - medium gray-brown; firm to slightly hard; very silty; medium to well indurated; noncalcareous; medium to large, platy, tabular fragments with poor lamination; fissile in part; prominent white to beige foram ghosts, some recrystallized; very homogeneous; very weak yellow-green background sample fluorescence; very poor to weak, slow spotty yellow cut fluorescence; no streamers; lacking petroleum odor or staining.

5130' SHALE - medium gray to gray-brown; firm to very hard; slightly platy, flat tabular cuttings; gritty in part; sucrosic texture; slightly calcareous; reduced occurrence of foram ghosts; recrystallized to some extent; weakly laminated; no sample fluorescence; very weak extremely spotty pale yellow background fluorescence; no petroleum odor.

5140' SHALE - dark gray-brown; slightly firm to hard; overall moderately well indurated; cuttings are dominantly medium sized blocky tabs, some exhibit irregular subparallel bedding, with occasional calcareous rich layers; slightly gritty to smooth texture; dull earthy luster; micaceous; trace pyrite in dolostone; pale yellow background sample fluorescence.

5150' DOLOSTONE - tan, buff; hard; well indurated; sharp hackly fracture; commonly has light to dark microlaminations; grainy to microcrystalline texture; resinous to subvitreous luster; scattered mica and dark heavy inclusion; strong trace pyrite nodules on surface; trace yellow mineral fluorescence from clay; persistent pale yellow sample fluorescence; slightly brighter cut fluorescence.

5160' SHALE - very rich, dark brown to chocolate brown; firm to hard; moderate to well indurated; very small to medium, subangular to rounded, slightly platy to tabular cuttings; slightly waxy to sparkling luster; occasionally dull; very gritty to grainy texture; softer fragments exhibit a slightly punky appearance; indistinct foram ghosts; moderate, uneven fissility; low apparent porosity; slightly calcareous in places; generally homogeneous; very pale yellow background sample fluorescence; slow, diffuse, pale green to green-yellow cut fluorescence following repeated cut attempts; very weak indistinct yellow residual cut fluorescence; no live oil pops or oil sheen.

5170' LIMESTONE - gray-tan, cream bone white; very hard; sharp, subangular, brittle, tabular and blocky cuttings; slightly waxy to sparkling luster; grainy to slightly sucrosic texture; commonly light gray silty; microcrystalline; lense; weak trace microfractures; occasionally silty laminations; slightly dolomitic; oil as above.

5180' SHALE - medium gray-brown to dark brown; firm to increasingly hard; moderate to well indurated; small to medium, slightly larger, subangular to subrounded, tabular cuttings; sparkling luster; very gritty to grainy texture; very silty; occasionally light tan slightly dolomitic fragments; very micaceous; poor fissility; infrequent calcareous inclusions; dense; poor apparent porosity; persistent limestone fragments; very pale yellow sample fluorescence; weak to indistinct pale green cut fluorescence following repeated cut attempts.

5190' CLAY - very dark brown; predominantly very soft; thin to decreasingly thick, slightly pasty to liquid consistency; very good solubility; very gritty texture; sticky in places; extremely silty; infrequently small, soft, malleable nodules; shale exhibits poor quality of oil indicators as above.

5200' LIMESTONE - dirty white, tan, and bone white; commonly gray streaks; very hard; brittle; sharp, angular to subangular cuttings; slightly pearly to resinous luster; fine abrasive to occasionally grainy texture; minor hackly fracture; predominantly microcrystalline; occasionally silty streaks; trace laminations; slightly dolomitic; lacking distinct mineral fluorescence; moderate HCl reaction; oil as above.

5210' SHALE - medium brown, dark chestnut brown and less frequently very dark brown; slightly firm to hard; moderately to well indurated; very small to medium subangular to subrounded cuttings; slightly sparkling to dull luster; gritty to abrasive texture; micaceous; weak trace foram ghosts; poor fissility; common limestone fragments; minor hackly fracture; very pale yellow background sample fluorescence; very weak, indistinct diffuse yellow to yellow-green cut fluorescence following repeated cut attempts; very weak pale yellow residual cut fluorescence.

5220' LIMESTONE - medium gray to bone white; very hard; sharp, angular, brittle, blocky cuttings; slightly sparkling; sucrosic to very rough abrasive texture; slightly silty in places; predominantly microcrystalline; common hackly fracture; occasionally soft marl fragments; indistinct pale yellow background sample fluorescence; slight improvement in pale green cut fluorescence.

5230' SHALE - medium gray-brown and chestnut brown; firm to hard; moderate to well indurated; very small to medium, subangular, slightly platy to tabular cuttings; sparkling luster; occasionally dull; abrasive to gritty texture; softer cuttings have slightly diatomaceous appearance; trace cuttings with abundant foram debris; poor to moderate fissility; very micaceous; persistent limestone streaks; very pale yellow sample fluorescence; slow, diffuse pale green to green-yellow cut fluorescence following repeated cut attempts.

5240' SHALE - medium to slightly chestnut brown; firm to slightly hard; moderately indurated; commonly slightly soft to firm; slightly punky cuttings; occasionally grades to firm mudstone; sparkling luster; abrasive texture; micaceous; minor trace pyrite; poor fissility; very pale yellow background sample fluorescence; intensity of sample fluorescence slightly more pronounced; very weak diffuse pale green-yellow cut fluorescence.

5250' SHALE - dark brown; dominantly soft; very firm in places; poor to moderate induration; shows platy fissility when broken; more firm cuttings have light to dark microlayers; smooth to gritty texture; dull earthy luster sparkling with tiny mica inclusions; noncalcareous; limestone is dolomitic with trace pyrite nodules; strong trace yellow clay mineral fluorescence; very weak pale yellow background sample and cut fluorescence.

5260' CLAY - dark brown; thick, moderately pasty, weakly stiff consistency; slightly sticky, abrasive texture due to high, sharp, firm shale content; easily soluble; noncalcareous; trace small, slightly firm, malleable nodules with poor solubility; trace insoluble white marly clay; trace glauconitic claystone; well indurated shale contains scattered medium size impure calcite inclusions; weak pale yellow background sample and cut fluorescence.

5270' SHALE - dark to medium gray, trace gray-green; hard to slightly soft; induration ranges from moderately well to poor; exhibits irregular incipient to well defined platy fissility; slightly grainy to smooth texture; resinous to dull earthy luster; trace calcite inclusions weathered to calcareous rich clay; micaceous; slight increase in very small dolomitic limestone from last sample; trace forams; weak yellow organic sample fluorescence.

5280' DOLOSTONE/LIMESTONE - light to medium brown; very hard; well indurated; sharp uneven fracturing, weakly laminated in places; rough, nonuniform texture; resinous luster; occasionally lighter, more pure layers; trace mica and small dark inclusions; trace free weakly calcareous kaolinite nodules; persistent weak yellow background sample cut fluorescence.

5290' SHALE - rich dark brown to medium brown; overall firm, darker cuttings less firm; moderate induration; dominantly rough, incipient bedding with frequent sharp fragments showing regular planar fissility; smooth to gritty texture; dull earthy luster is prominent; less frequently resinous; scattered mica inclusions; trace calcite; kaolinite still limited to trace amounts; decrease pale yellow sample fluorescence.

5300' CLAY - dark brown; less thick pasty consistency; weakly gummy, more abrasive texture resulting from slight increase in hard limestone content; moderately good solubility; very slightly calcareous; limestone grades from very argillaceous to dolomitic with occasional pyrite inclusions; oil shows limited to pale yellow sample fluorescence from original rich shale.

5310' SHALE - dark to medium brown; very firm to soft; overall fair induration, occasionally poor; dominantly blocky tabular cuttings with sharp edges; irregular layering; frequent phosphatic material; occasionally weathered calcareous inclusions; trace kaolinite; decrease spotty pale yellow sample fluorescence.

5320' LIMESTONE - white, buff, light to medium brown; few cuttings are much more pure; hard to firm; well indurated; slightly more fractured appearance than previous samples; more impure fragments have irregular microlaminations of more pure limestone; rough texture with pyrite and mica inclusions; overall resinous; sparkling in places.

5330' CLAY - dark olive brown; less thick, slightly runny consistency; weakly sticky, abrasive texture; very few soft, easily malleable, poorly soluble nodules; very slightly calcareous; expands poorly when hydrated; phosphatic material abundant on well indurated shale; pale yellow sample fluorescence.

5340' LIMESTONE - cream to bone white; very hard; very small to medium, sharp, angular; slightly pearly to waxy luster; occasionally sparkling; sucrosic to slightly grainy texture; microfissile; pure; infrequent cuttings exhibit silty laminations; occasionally shiny pyritized foram remnants; shale fraction is very gritty and coarse silty in appearance; weak trace blocky pyrite fragments; very weak pale yellow background sample fluorescence; very slow diffuse pale green to green-yellow cut fluorescence following repeated cut attempts.

5350' SHALE - medium to very dark brown and gray-brown; hard to slightly firm; moderate to well indurated; very small to medium, subangular to subrounded; slightly platy to tabular cuttings; dull to slightly sparkling luster; fine abrasive to gritty texture; micaceous; slightly hackly fracture; minor trace foram inclusions; trace free pyrite; oil as above.

5360' CLAY - very dark brown to gray-brown; soft to slightly stiff; very thick pasty consistency; moderate to good solubility; gritty texture; very silty; minor trace nodules; shale exhibits very pale yellow sample fluorescence.

5370' SANDSTONE - white to light gray; extremely fine to gritty; angularity and sphericity not determinable; moderate to well sorted; moderately apparent porosity; very silty; slightly micaceous; trace calcareous cement; friable; predominantly quartz; common limestone fragments; infrequent limestone contain trace dark brown slightly sticky oil; slickensides observed as minor isolated shale fragments; scattered pale yellow sample fluorescence; weak diffuse pale green-yellow cut fluorescence generally observed following separated cut attempts.

5380' SHALE - very rich dark brown; slightly firm to hard; moderate to well indurated; small to medium, subangular to subrounded, tabular cuttings; slightly dull to sparkling luster; abrasive texture; occasionally punky fragments; commonly exhibits coarse silty surface appearance; minor foram inclusions; persistent trace pyrite; limestone continues to have isolated cuttings with minor dark brown oil stains; dull yellow sample fluorescence; weak, diffuse, pale green to green-yellow cut fluorescence following repeated cut attempts.

5390' SHALE - very dark brown; firm to hard; moderate to well indurated; slightly punky in places; trace slickensides; minor pyritized microfossils; very fine grain sandstone does not exceed 5% in amount; persistent sharp angular limestone fragments; lacking distinct visible oil staining; pale yellow sample fluorescence; weak yellow-green cut fluorescence following repeated cuts.

5400' SANDSTONE - light gray to white; extremely fine to very fine to gritty; moderately sorted; silty; soft, friable cuttings; predominantly quartz; sugary appearance; minor biotite; trace pyrite; common small or foram tests; lacking discernible oil stains; very pale yellow sample fluorescence; weak, diffuse pale green to green-yellow cut fluorescence following repeated cuts.

5410' LIMESTONE - bone white to cream; very hard; very small, sharp, angular, brittle subrounded; slightly pearly luster; slightly smooth to sucrosic texture; weak trace laminations; minor vugs; slight splintery fracture; persistent trace slight arenaceous appearing foram tests; very pale yellow sample fluorescence; slow, diffuse weak green-yellow cut fluorescence.

5420' SHALE - very dark brown; firm to hard; persistent slightly soft; punky to crunchy cuttings; moderate to strong sparkling luster; very grainy texture; trace slickensides; persistent pyrite; common broken foram tests; very micaceous; occasionally having a phyllitic-like luster; minor hairline fracture on harder fragments; abundant thin limestone shards; persistent trace extremely fine to gritty, soft, friable slightly silty light gray sandstone cuttings; very pale yellow sample fluorescence.

5430' LIMESTONE - light brown, light gray-brown; very hard to firm; fair induration; sharp, hackly fracture; weakly laminated; microcrystalline to grainy texture; resinous to sparkling luster; occasionally phosphatic material; trace carbonaceous material; transparent pale yellow cut fluorescence.

5440' SAND - clear, white, tan; extremely fine to coarse; very angular to subangular; very poorly sorted; low to moderate sphericity; quartz is major constituent with abundant very fine grained moderately friable sandstone with noncalcareous argillaceous matrix; trace very weak yellow background sample fluorescence; very slow yellow pale cut fluorescence; confined to shale; no pops; no odor.

5450' SANDSTONE - buff to yellow-brown; soft to slightly firm; extremely fine; very angular to subrounded; well sorted; fair sphericity; dominantly quartz with kaolinitic matrix; fair induration; trace calcareous; lacking cut fluorescence or sample fluorescence; fluorescence is confined to shales.

5455' LIMESTONE - few cuttings are slightly more pure hard; occasional microlaminations; irregular, sharp fracturing; sucrosic to microcrystalline texture, sparkly to resinous luster; reacts violently to acid; trace pyrite in fractures; abundant forams in several fragments; pale yellow mineral fluorescence from limestone masks possible sample fluorescence.

5460' SHALE - dark to medium brown; small to large cuttings; very firm to soft; predominantly moderate to well indurated; cuttings generally exhibit incipient bedding with occasionally having stair-stepped, planar layering; slightly gritty to grainy texture; dull earthy to sparkly luster where more arenaceous; calcareous where white limey blebs are present; micaceous; very pale yellow cut fluorescence.

5470' CLAY - rich dark brown; moderately thick, slightly stiff consistency; greasy, sticky, abrasive texture due mostly to hard, sharp limestone and shale cuttings; fair solubility; slightly calcareous; medium size rounded, firm, gritty; poorly soluble nodules grading to claystone; trace pyrite in washed sample; frequent forams from desilter; spotty mineral fluorescence; no discernible sample or cut fluorescence.

5475' SAND - clear, white, tan; very fine to coarse grained; very angular to subangular; extremely poorly sorted, very low sphericity in coarser grains moderate overall; dominantly quartz, more fine is from well sorted friable sandstone with fair apparent porosity; occasional forams, both as inclusions and free; weak mineral fluorescence; no oil indicators.

5480' SHALE - rich dark brown to moderately brown; hard to very soft; well indurated overall with occasional easily broken cuttings; dominantly blocky tabs with occasional good visible internal fissility; gritty to arenaceous texture; dull earthy to sparkling luster where abundantly scattered mica inclusions are present; very frequent preserved foram inclusions; no discernible oil shows.

5485' LIMESTONE - tan, medium brown; hard to very hard; well indurated; sharp irregular fracturing; less frequent lighter microlaminations; very argillaceous in places; sucrosic to occasionally microcrystalline texture; resinous to sparkling luster in more grainy fragments; very frequently cuttings contain abundant scattered foram inclusions; occasionally free kaolinite and as inclusions in shale; strong trace pale yellow mineral fluorescence; no sample or cut fluorescence.

5490' SHALE - very dark brown; slightly firm to predominantly hard; moderate to well indurated; very small to medium subangular to subrounded, predominantly tabular cuttings; slightly sparkling to dull luster; fine abrasive texture; occasionally punky cuttings; minor calcareous laminations and inclusions; slightly silty; micaceous; weak trace loose foram tests; minor trace pyrite; persistent trace limestone; no cut fluorescence.

5500' CLAY - dark brown; slightly stiff to predominantly soft; slightly thick pasty consistency; moderate to good solubility; silty; slightly sticky; gritty; slightly punky; minor trace soft to firm, chunky claystone cuttings; no cut fluorescence.

5510' SAND - clear to light brown; upper to lower fine grain; subangular to rounded; moderate to moderately well sorted; spherical to subprismoidal; predominantly loose quartz; minor trace biotites; ditch sample shows infrequent friable weakly cemented quartz sandstone cuttings; very weak spotty yellow background sample fluorescence; very slow, weak, diffuse pale green-yellow cut fluorescence following repeated cut attempts.

5520' CLAY - very dark brown to gray-brown; soft to slightly stiff; very thick, pasty consistency; moderate to good solubility; very gritty texture; very silty; slightly sticky; moderate to good cohesion; occasional greasy feel; common medium to large size sloughing shale; shale exhibits all as above.

5530' SHALE - very dark brown to dark chestnut brown; slightly firm to hard; slightly crunchy; very small to medium, subangular to subrounded, irregular tabular cuttings; predominantly sparkling luster; fine abrasive to gritty texture; occasional foram rich cuttings; decrease frequency of loose foram tests; predominantly uneven fissility; weak trace phosphatic inclusions; trace pyritized microfossils and loose pyrite fragments; marked increase in abundance of fine to upper very fine grain quality solubility; persistent trace poor oil indicators as above.

5540' SAND - clear and white; upper very fine to upper fine grained; subangular to moderately well indurated; subprismoidal to subdiscoidal; moderately sorted; predominantly loose quality; common biotite flakes; overall sample becoming increasingly clayey; trace forams; very weak yellow sample fluorescence.

5550' SHALE - very dark brown to dark chestnut brown; slightly firm to predominantly hard; slightly crunchy; very small to medium, subangular to subrounded, tabular cuttings; moderate, uneven fissility; resinous to sparkling luster; gritty texture; abundant forams; trace cuttings exhibit foram; very pale yellow sample fluorescence.

5560' SHALE - dark to medium brown; very firm to soft; dominantly moderately well indurated, occasionally very poor; abundant cuttings showing incipient bedding; few with good fissility smooth to arenaceous texture; dull earthy luster sparkling frequently with pinpoint mica inclusions; abundant forams; trace fish scales; no sample or cut fluorescence.

5570' CLAY - dark brown to gray; thick, stiff, slightly pasty consistency; gummy, sticky, gritty texture; moderately good cohesion; fair solubility; small; soft; rounded claystone nodules with very poor solubility; noncalcareous; shale contains infrequent kaolinite inclusions and abundant preserved and relict forams; trace phosphates; sample lacks oil indicators.

5580' SHALE - medium to dark brown-gray; light to medium gray when dry; firm overall, very soft in places; fair induration; slight increase fissility; irregular subplanar bedding; decreasingly arenaceous; prominent texture is slightly gritty with dull earthy luster; scattered mica and foram inclusions; no discernible sample or cut fluorescence.

5590' SAND - clear, white, amber; very fine to medium grained; very angular to subangular; moderate sorting; low sphericity in medium size grains; indiscernible in smaller; dominantly unconsolidated quartz; no visible sandstone fragments; occasional pyrite in trace limestone fragments.

5600' SHALE - medium brown-gray to brown; firm to slightly soft; trace calcareous; medium to fine platy cuttings; dull earthy texture; trace sucrosic appearance; prominent microfossils; weakly to strongly laminated; fair fissility; fair induration; trace very weak yellow mineral fluorescence; lacking cut fluorescence; no oil fluorescence; no pops.

5605' SANDSTONE - light gray to gray-brown; very fine to fine; subrounded to subangular; fair sorting; fair sphericity; dominantly quartz with trace clay matrix; dominantly noncalcareous; structureless; trace silt; lacking oil fluorescence; trace bright yellow mineral fluorescence.

5610' CLAY - medium gray-brown; soft, runny consistency; smooth, slightly greasy texture; noncalcareous; nodules are small, rounded; soft slimey, very poorly soluble to insoluble; sand is primarily very fine grained, angular, very well sorted unconsolidated quartz grains; weak trace kaolinite; spotty bright yellow-green mineral fluorescence from clay; no identifiable oil indicators.

5620' SANDSTONE - tan; very fine to fine grained; angular; well sorted; extremely easily friable; dominantly quartz, with glauconite and only trace limestone; clay matrix; desilter sample 95% sand; no sample or cut fluorescence.

5625' SHALE - medium to dark brown-gray; soft to firm; fair induration is prominent with occasional well indurated fragments; persistent blocky tabular cuttings with incipient to stair-step fissility; slightly gritty texture; dull earthy luster; less frequent mica flakes.

5630' SHALE - medium to dark gray; medium to fine, slightly molded cuttings; fair to well indurated; slightly calcareous on some internal fractures; weakly laminated; poorly fissile; possibly slightly porcelaneous; abundant clay fraction of sample may represent fine broken and disseminated shale fragments; no oil fluorescence; no mineral fluorescence.

5635' CLAY - medium gray to slightly brownish-gray; soft; slightly sticky; massive, lacking nodules, very pasty, thick consistency; slightly gritty consistency due to contained sand grains; poorly soluble; no oil fluorescence.

5660' CLAY - light to medium gray and brown-gray; very soft; thick pasty consistency; poor to moderate solubility; very smooth texture; slightly silty; very greasy; creamy; generally has a wall cake-like appearance; slightly kaolinitic; clay percentage appears to be anomalously high; very fine grain sand output from desander appears to be increasing; no oil or cut fluorescence.

5665' SAND - overall sand sample is light gray; individual grain are predominantly clear; upper very fine to lower fine grain; angular to subrounded; subparamoidal to spherical; moderate to well sorted; silty; predominantly loose, clear quartz; trace feldspar; minor biotite; abundant black lithic grain; lacking discernible accessory minerals; actual sand percentage from ditch sample is only 20% of total sample; output from desander is 100% sand and appears to be increasing in volume; evidence from drill rate and desander indicates actual percentage of sand should be markedly higher than that represented from the ditch sample.

5675' SAND - light to medium gray and clear; upper fine to upper very fine grained; occasionally lower medium grain; subangular to increasingly rounded; spherical to subprismoidal; moderately to increasingly well sorted; predominantly, loose clear quartz; lacking significant accessory minerals; commonly dark brown to black-brown lithic grain; slightly silty; kaolinitic clay matrix; clay percentage continues to be anomalously high; no oil or cut fluorescence.

5680' SAND - light gray and clear; lower to upper fine grain; subangular to subrounded; spherical to subdiscoidal; well sorted; predominantly loose clear quartz; trace feldspars; abundant lithic grain; minor trace biotite; continued abundance of greasy, kaolinitic clay matrix; no oil or cut fluorescence.

5690' CLAY - light to medium gray; very soft; thick pasty consistency; poor to moderately solubility; smooth texture; silty; kaolinitic; greasy; wall cake-like appearance; abundant very fine grain sand from desander; no cut fluorescence.

5710' SAND - light brown-gray overall; very fine to fine to occasionally medium; angular to subangular; moderate sphericity; loose; kaolinitic; vitreous quartz; white feldspars; abundant dark lithic mafic quartzitic; scattered calcite; no oil stain or fluorescence; no pops, sheen, odor.

5770' SHALE - medium to dark brown; firm to hard and bright; flaky to blocky, rare cuttings; clayey to silty and sparkling; occasional slightly resinous; occasional forams; massive to flaky fissility; occasional good planar parting; associated tan, hard dolostone cuttings; occasional dolomitic crystalline aggregates; dull orange carbonate mineral fluorescence; possibly very weak diffuse bulk cut fluorescence; no cut from individual grains.

5810' SHALE - very dark brown; firm to hard; moderate to well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling to slightly resinous luster; abrasive to grainy texture; silty; moderate, uneven fissility; low apparent porosity; common white calcareous inclusions; common loose quartz grains; no oil or cut fluorescence.

7820' CLAY - medium gray; soft; slightly low density; moderately malleable; cohesive; nonnodular; gritty; fair solubility; moderately calcareous; abundant fine grain quartz, feldspars, lithic grains; scattered sporbo; slightly expansive in #20; no oil.

5830' SANDSTONE - light gray; friable; very fine to medium; angular to subangular; moderate sphericity; moderately sorted; grades to dominantly matrix; kaolinitic; slightly calcareous; abundant vitreous quartz; white feldspars; abundantly dark lithics; commonly microsporbo; no stain or cut fluorescence; no odor, iridescence from blender; trace orange, pyritic tuff; common dolomitic limestone cuttings; trace odor at shakers; occasional iridescent pop.

5840' LIMESTONE - light gray to tan; hard, angular cuttings; resinous; argillaceous; commonly dolomitic; occasionally clear, crystalline calcite; occasional mineral fluorescence; no oil or cut fluorescence; trace weak green-yellow bulk cut fluorescence; weak gray to yellow residual cut fluorescence.

5850' SHALE - becoming commonly yellow-gray, translucent, tuffaceous; slightly soft; waxy; noncalcareous; abundant inclusions; weak yellow mineral fluorescence; no oil.

5860' CLAY - medium gray; slightly thick, soft; smooth to nonnodular; poor to fair cohesion, malleable; slightly expansive; soluble; noncalcareous; silty and sandy; scattered microsporbo; occasional bulk cut fluorescence, probably pipe dope.

5870' SHALE - dark brown; firm to hard and brittle; massive to flaky, elongated cuttings; occasionally slightly hackly; rare siliceous cutting; common light gray, tuffaceous cuttings; occasionally silty; noncalcareous; scattered fish parts; very fine disseminated pyrite; rare discernible foram; overall poor to fair fissility; no oil or cut fluorescence.

5880' SANDSTONE - white, light gray, rarely light brown; fine lower to medium lower; angular; dominantly subdiscoidal; moderately soft; abundant kaolinitic matrix; increasingly calcareous; fair apparent porosity to friable cuttings; commonly tight; abundant feldspars; green, black, red lithics; quartz; no oil.

5890' SHALE - medium to dark brown, occasional red tint; increase large blocky, massive cuttings; hard; noncalcareous; commonly gray, silty and sandy grading to siltstone; commonly sparkling, slightly siliceous appearance; no oil.

5900' CLAY - medium gray; soft, slightly thick consistency; weakly sticky, gritty texture due to sandstone and shale content; moderate to poor cohesion; easily soluble; very slightly calcareous; no discernible nodules; trace feldspar igneous rock fragments with amphibole inclusions; no sample fluorescence; very weak pale yellow cut fluorescence.

5910' SAND - clear, white, gray-black; very fine lower to very coarse lower; very angular to subrounded; extremely poor sorting dominantly subprismoidal; quartz is major consistency, abundantly white, tan, gray lithic fragments including sandstone and tuff; frequently gray to white feldspar; moderately to easily friable; one shale cutting with oil staining has no sample fluorescence; very fast bright white-yellow cut fluorescence; dark straw visible cut.

5920' SHALE - dark gray-brown; firm to slightly soft; moderately well indurated; blocky, tabular cuttings; irregular fissility, occasional stair-step layering; slightly gritty to grainy texture; dull earthy luster; sparkling with scattered mica flakes; occasional calcareous inclusions; scattered sporbo; trace live pops; faint oil odor; no discernible sample fluorescence; very slow weak diffuse yellow-green cut fluorescence.

5990' SILTSTONE - medium gray to brown-gray; firm to hard; moderate to well indurated; medium, subangular, tabular cuttings; strong sparkling luster; fine abrasive to gritty texture; very micaceous; poor shaly partings; common sharp contacts with calcareous sandstone; weak trace kaolinitic fragments; trace spotty yellow sample fluorescence; weak trace pale green sample fluorescence following repeated cuts.

6000' CLAY - medium gray; very soft; thin slightly pasty consistency; moderate solubility; smooth to slightly abrasive texture; silty; creamy; slightly sticky; greasy; slightly kaolinitic; minor trace spotty sample fluorescence.

6010' SANDSTONE - white and light gray; upper fine to upper medium grain; angular to subrounded; moderately sorted; tight; friable; trace calcareous cement; predominantly quartz; common lithics; moderate apparent porosity; abundant biotite flakes probably representative of LCM contamination; pale spotty yellow sample fluorescence; weak pale green cut fluorescence following repeated cut attempts.

6020' SHALE - medium gray to gray-brown; hard; moderate to well indurated; small to predominantly medium; subangular to subrounded, tabular cuttings; sparkling luster; abrasive to gritty texture; low apparent porosity; very silty and finely sandy; slightly calcareous; very micaceous; poor to moderate uneven fissility; no oil or cut fluorescence.

6030' SANDSTONE - white and light gray; lower fine to upper medium grain; angular to subangular grain; poor to moderate sorting; spherical to subdiscoidal; commonly loose grain; frequently tight, slightly calcareous, slightly friable cuttings; moderate apparent porosity; predominantly quartz; trace heavy minerals and lithic grain; indistinct pale spotty yellow sample fluorescence.

6080' SAND - clear, white and light gray; lower fine to upper medium; moderately sorted; spherical to subdiscoidal; predominantly loose; commonly tight; calcareous; low porosity; silty sandstone cuttings; predominantly quartz; trace heavy minerals and lithic grain; occasionally grades to very sandy siltstone; no cut fluorescence.

6090' SHALE - medium gray to gray-brown; hard; well indurated; small to predominantly medium, subangular to subrounded, very tabular cuttings; strong sparkling luster; fine abrasive to sucrosic texture; common calcareous streaks; very micromicaceous; poor fissility; commonly sandy streaks; very silty; low apparent porosity; no cut fluorescence.

6200' LIMESTONE - yellow-brown; hard; small; angular cuttings; sparkling to resinous; crystalline; occasional vugs; sandy; commonly grades to sandstone; sample overall increasingly limey; dull orange mineral fluorescence; no oil; scattered tuff.

6210' SANDSTONE - light gray; hard to friable; very fine to medium; angular; spherical to subdiscoidal; moderately well sorted; commonly very hard and calcareous, occasionally grading to sandy limestone; abundant kaolinite; dominantly tight; dominantly vitreous quartz; abundant feldspar; lithics; occasional shell fragments; no oil.

6220' CLAY - medium gray; becoming very soft and low density; slippery texture; increase amounts; soluble; expansive; calcareous; very silty, sandy; no oil; poor sample.

6240' SANDSTONE - light gray, light yellow-brown and white; lower very fine to upper fine grain; subprismoidal to subdiscoidal; poor to moderately sorted; very well indurated; hard; tight; commonly strong calcareous cement; occasionally siliceous; more friable fraction represented by loose quartz grain; light yellow-brown cuttings generally very silty; appears to exhibit tendency to cleave along subparallel planes; predominantly quartz; trace feldspars; common heavy minerals; frequent distinct biotite inclusions; matrix is slightly kaolinitic; trace siltstone cuttings contain foram debris; very pale yellow to yellow-gold sample fluorescence; weak, diffuse green cut fluorescence observed following crushing of sample; initial cut prior to crushing of sample resulted in no fluorescence.

6250' CLAY - medium gray to slightly brown-gray; very soft; thin to slightly thick pasty consistency; moderately soluble; very gritty to abrasive texture; silty; commonly very fine grain sand; slightly kaolinitic; sticky; slightly creamy; very weak trace small soft nodular clay masses; no live oil pops or iridescent oil sheen; sample and cut fluorescence from sandstone cuttings similar to those of previous sample.

6260' SANDSTONE - light yellow-brown to gray; lower fine to upper medium; poor to moderately sorted; spheritic to discoidal; very tight; well indurated; very calcareous; silty; slightly kaolinitic; predominantly quartz; trace biotite; weak pale green cut fluorescence following crushing of sample.

6270' SILTSTONE - medium gray to brown-gray; very moderately well indurated; slightly brittle; medium, subangular to subrounded, tabular cuttings; sparkling luster; very gritty texture; common very fine sandy streaks; trace calcareous laminations; common forams; very weak trace pale yellow sample fluorescence.

6280' SHALE - medium brown to slightly chestnut brown; very hard; well indurated; slightly brittle; small to medium, subangular to subrounded, tabular to slightly platy cuttings; slightly waxy to strong sparkling luster; very abrasive to grainy texture; common forams; calcareous; silty; minor hackly fracture; no oil or cut fluorescence.

6290' LIMESTONE - light yellow brown ;to cream; very hard; small to medium, angular to subrounded, tabular to slightly blocky cuttings; slightly sparkling to pearly luster; slightly sucrosic to grainy texture; slightly sandy; silty; moderate HCL reaction; trace foram inclusions; pale yellow mineral fluorescence; no cut fluorescence.

6300' SAND - white, light gray and light yellow-brown; lower fine to upper medium, subangular to rounded; moderate to well sorted; spherical to subdiscoidal; loose; calcareous overgrowths; probably represents well compacted, relatively tight, friable sandstone; predominantly quartz; trace biotite; commonly well rounded lithic grain; weak trace pale yellow sample fluorescence; slow diffuse pale green cut fluorescence following repeated cuts.

6310' SHALE - medium to chestnut brown; hard; well indurated; small to medium, tabular cuttings; sparkling luster; gritty to grainy texture; abundantly very fine grained sand; silty; trace silty to sandy limestone; common forams; weak trace pale yellow sample fluorescence.

6320' SILTSTONE - medium gray; gray-brown and brown; hard to very hard; well indurated; grade to very sandy siltstone to silty very fine grained sandstone; grainy texture; poor fissility; micaceous; trace forams; minor trace limestone; no cut fluorescence.

6330' SANDSTONE - light brown and gray; lower very fine to lower fine; poorly sorted; spherical; very calcareous; very tight; low apparent porosity; exhibits tendency to cleave along preferred subparallel planes; very silty; micaceous; abundant quartz; trace heavy minerals and lithic grain; trace pale yellow mineral fluorescence; no cut fluorescence.

6340' SANDSTONE - gray, gray and brown; mottled; very fine to occasionally medium; predominantly fine; appears subangular in cuttings; poor sorting; grades to sandy shale with spotty pockets of clean sand; well indurated; tight; slightly calcareous quartz with local abundant lithic fragments; very faint pale yellow mineral sample fluorescence; rare extremely slow extremely diffuse pale yellow cut fluorescence; no visible cut.

6350' SANDSTONE - white, gray, black; medium to granule; conglomerate; subangular to rounded; poor to fair sphericity; poorly sorted; moderate to moderately well indurated; calcareous cement with common calcite crystallines; fair apparent porosity; quartz and lithic fragments.

6360' SAND - clear, white, light gray and light brown; lower fine to upper medium; subangular to rounded; spherical to discoidal; moderately sorted; loose; infrequently tight; calcareous cuttings; sandstone cuttings commonly grade to siltstone; predominantly quartz; trace lithic grain and heavy mineral; weak trace pale yellow sample fluorescence; slow, weak, diffuse pale green cut fluorescence following repeated cut attempts.

6370' SILTSTONE - medium brown and gray-brown; hard; well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling luster; gritty to abrasive texture; slightly micaceous; abundant very fine grained quartz; trace calcareous inclusions; slightly shaly partings; micaceous; very weak pale yellow sample fluorescence.

6380' CLAY - medium to dark brown-gray; soft to increasingly stiff; thick pasty consistency; moderate to good solubility; very gritty to abrasive texture; silty to very fine to sandy; slightly sticky; weak trace soft, malleable nodules; no live oil pops or oil sheen; shale and sandstone exhibit indistinct pale yellow sample fluorescence.

6390' SHALE - medium to dark brown and chestnut brown; slightly firm to hard; overall decrease in hardness; moderate to well induration; small to medium, subangular, tabular cuttings; slightly sparkling to resinous luster; slightly gritty to grainy texture; silty; slightly micaceous; occasionally calcareous inclusions; weak trace foram debris; occasional crunchy to slightly punky; moderate, uneven fissility; trace sandy streaks; decrease abundance of loose, very fine to medium grained sand; weak trace pale yellow sample fluorescence; pale green cut fluorescence with difficulty.

6400' LIMESTONE - cream, tan and brown; hard; small to medium, angular to subangular, blocky cuttings; slightly sparkling to resinous luster; slightly grainy texture; impure; nonlaminated; trace foram increase; silty; no cut fluorescence.

6410' CLAY - dark brown-gray, increasingly stiff to soft; very thick, pasty consistency; moderate to good solubility; gritty texture; very silty; sticky; moderate to good cohesion; decrease sand content; slight increase in soft malleable nodules; no cut fluorescence.

6420' SHALE - medium to dark brown; firm to hard; moderate to well indurated; occasionally slightly crunchy to infrequently punky; very small to medium, subangular to subrounded, tabular cuttings; slightly waxy to sparkling luster; abrasive to grainy texture; poor to moderate uneven fissility; micaceous; calcareous; trace indistinct foram debris; minor inclusions of calcareous clasts; occasionally very fine to sandy; predominantly very silty; no cut fluorescence.

6430' SILTSTONE - medium brown to gray-brown; firm to hard; blocky occasionally tabular with fair shaly partings; dull luster; rough gritty texture; occasionally sandy; moderately calcareous with visible tan colored calcareous inclusions; occasionally very faint yellow mineral fluorescence; no sample or cut fluorescence.

6440' SHALE - dark brown, dark gray-brown; moderately indurated; crumbly to very tough; dull luster becoming increasingly earthy; rough gritty texture; very silty grading to siltstone; scattered sporbo in more earthy cuttings; moderately calcareous; no sample or cut fluorescence.

6450' SANDSTONE - dark brown; grades from silt sized to occasionally medium grained; larger clasts are predominantly sporbo; average grain size is fine; poorly sorted blocky cuttings; moderate to moderately well indurated; calcareous; very weak cut from better sorted cuttings.

6460' SANDSTONE - medium brownish-gray; fine; subangular; moderately well sorted; well indurated grain packed; tight; slightly to moderately calcareous; quartz feldspar and commonly dark lithics; occasional cuttings contain abundant fine to medium sporbo; commonly grading to dark brown siltstone; no sample fluorescence; slow extremely weak extremely faint wispy streaming yellowish cut fluorescence; no visible cut; none to extremely faint orange-yellow residual cut fluorescence.

6470' SILTSTONE - dark gray-brown; firm to slightly soft; moderately well indurated; cuttings range from rounded subspherical to blocky tabs, occasionally shows subparallel stair-step fissility; slightly gritty texture; dull earthy luster sparkling with frequent pinpoint mica inclusion; occasional white limey blebs indicating possible relict forams; trace kaolinite strong trace dolomitic limestone; no sample fluorescence; extremely weak slow pale yellow cut fluorescence.

6480' SAND - white, light gray; fine to medium grained; very angular to subrounded, moderately sorted; prismoidal to subspherical; good apparent porosity, easily absorbs water; dominantly quartz and feldspar with frequent lithics; weak calcareous cement; trace dark orange sample fluorescence; very weak yellow-green cut fluorescence.

6490' LIMESTONE - light to medium brown; hard, brittle; sharp cuttings with irregular fracturing; microcrystalline to slightly grainy texture, resinous to sparkling luster; very argillaceous in places; occasionally calcareous seams in siltstone; infrequently poorly indurated claystone with punky texture; no sample fluorescence; very weak slow pale green cut fluorescence.

6500' SILTSTONE - medium to dark gray; firm, slightly brittle; crunchy; structureless to occasionally irregular fissile; slightly more gritty texture; dull earthy to infrequently faintly waxy luster; calcareous in places; trace limey blebs; common mica; no sample fluorescence; very weak pale green cut fluorescence.

6510' CLAY - medium gray; moderately thick, pasty, slightly stiff consistency; weakly gummy, abrasive texture due to well indurated siltstone cuttings; moderate to poor solubility; very slightly calcareous, infrequent medium size rounded, soft nodules with very poor solubility grading to claystone; no oil odor; no sample fluorescence; weak pale whittish-green cut fluorescence.

6520' SILTSTONE - medium gray; firm, slightly brittle; structureless, rounded cuttings to blocky tabs with incipient fissility; slightly gritty texture grading to occasional sandy, dull earthy luster; frequently mica, limey blebs are common; trace pyrite; trace sporbo; no oil smell; weak green cut fluorescence.

6530' SANDSTONE - white, gray; brittle, crunchy, upper very fine to lower medium grained; very angular to subrounded; moderately well sorted; subprismoidal to subspherical; fair apparent porosity; readily absorbs H20; quartz and feldspars are prominent with less abundant dark lithics; trace fossil possibly sharktooth.

6540' CLAY - pale gray; less thick, slightly runny consistency; pasty, abrasive texture; moderate cohesion; fair solubility; slightly calcareous; minor medium size very soft gritty nodules with poor solubility.

6550' SILTSTONE - medium gray; firm, slightly brittle; subrounded to blocky tabular cuttings generally structureless with occasionally good internal fissility grading to shale; gritty to slightly grainy texture; dull luster; calcareous in places; trace calcareous seams; no sample or cut fluorescence.

6560' SANDSTONE - white to light gray; very fine to fine grained; angular to subangular; moderate sorting; prismoidal to spherical; good apparent porosity, absorbs water immediately; dominantly quartz with abundant gray to white feldspar; common dark brown to black lithics, occasionally mica; trace sporbo; infrequently has kaolinitic matrix; no significant oil shows.

6570' SHALE - medium to light gray-brown; hard to very soft in places; brittle; overall moderately indurated; abundant incipient fissility, some show good internal layering upon breaking; silty texture; dull luster; trace phosphatic material, spotty bright white-green mineral fluorescence; no oil indicators.

6580' CLAY - medium gray; thick, moderately pasty, stiff consistency; soft, slightly abrasive texture; moderate solubility; no discernible nodules; very slightly calcareous; no sample or cut fluorescence.

6590' SHALE - dark gray-brown; firm to hard; moderate to well indurated; small to occasionally large, subangular to subrounded, tabular cuttings; sparkling luster; very finely abrasive to grainy texture; poor fissility; low apparent porosity; very silty; trace very fine grain sand; commonly calcareous; trace blocky microcrystalline limestone; generally lacks significant structure; no cut fluorescence.

6600' SILTSTONE - medium gray to gray-brown; firm to hard; moderate to well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling luster; gritty texture; structureless; very micaceous; occasionally grades to very fine grain silty sandstone; slightly calcareous; grades to silty shale; calcareous; indistinct white calcareous inclusions; no cut fluorescence.

6610' CLAY - dark gray to light brownish-gray; increasingly stiff; very thick, pasty consistency; moderate to good solubility; gritty texture; sticky; silty; moderate cohesion; nonnodular; no cut fluorescence; slightly calcareous.

6620' LIMESTONE - trace amounts; gray, cream, and bone white; very hard; coarse; slightly pearly to waxy luster; smooth to slightly sucrosic texture; microcrystalline; minor vugs; generally lacks significant structure; minor pale yellow mineral fluorescence; no oil or cut fluorescence.

6630' SANDSTONE - white, light gray and occasionally light brown; lower fine to lower medium grain; subangular to rounded; moderately sorted; slightly calcareous; commonly tight; low to moderate apparent porosity; predominantly quartz; trace heavy mineral and lithics; common loose quartz; trace biotite; slightly silty; trace kaolinitic matrix material; no cut fluorescence.

6650' SANDSTONE - pale brownish gray; salt and pepper; very fine to fine; subangular to subrounded; moderately well sorted; friable to moderately indurated; grain packed; slightly calcareous; dirty appearance; quartz and feldspar with common dark green-gray and black clasts, probably lithic fragments; minor pinkish shell fragments; occasional coarser cuttings with scattered glauconite; no sample fluorescence; infrequently very slow, very pale yellow cut fluorescence; no visible faint yellow residual cut fluorescence.

6660' SANDSTONE - medium gray to very dark gray to black; predominantly very fine to fine with occasional coarse and silt size grains; subangular with common subrounded to rounded clasts in darker cuttings; moderately sorted; predominantly moderate to moderately well indurated; occasionally friable; grain packed; poor apparent porosity; slightly calcareous; feldspar with clear quartz and common brown and dark gray lithics; darker, silty cuttings commonly contain sporbo; no sample fluorescence; very slow, very pale yellow cut fluorescence becoming slightly more intense with time; no visible moderately greenish-yellow residual cut fluorescence.

6660' LIMESTONE - gray-brown; hard, blocky; slightly resinous to microsucrosic along fractures; common mottled appearance; no bands or laminations; occasional crystalline fracture fill; minor vuggy porosity; rare trace oil stain; faint yellow mineral fluorescence; faint extremely weak yellow flash of cut fluorescence from stain cutting; no visible; very weak residual; trace medium brown oil stain on fractures in fine silty gray sandstone; instant opaque milky yellow cut fluorescence; amber visible cut dull orange-yellow residual cut fluorescence; medium brown residual ring.

6670' LIMESTONE - medium gray; hard; tabular to blocky; angular; dull to slightly sucrosic luster; microsucrosic texture; common white crystalline fracture fill; some waxy luster with white and gray bonding.

6670' SILTSTONE - medium gray, gray-brown; moderately well indurated; tabular to slightly blocky; gritty texture becoming sandy and grading to silty sandstone and silty shale; very slightly calcareous; no sample fluorescence; no visible cut fluorescence.

6680' SHALE - medium to dark brown; hard; tough to crumbly; dull luster; gritty abrasive texture; very silty; poor subparallel fissility; moderately calcareous; phosphatic with organic appearance; occasional visible forams; no visible microbanding; no sample fluorescence; extremely slow diffuse; very pale yellow cut fluorescence; no visible cut; extremely pale yellow residual.

6700' SILTSTONE - green-gray to brown; moderately indurated; crumbly to tough; blocky; dull luster; gritty abrasive texture; commonly grades to silty shale; slight to moderately calcareous in places; no sample fluorescence; rare trace extremely weak diffuse cut.

6710' SHALE - medium dark brown; moderately indurated; tough to slightly brittle; tabular; dull earthy luster; gritty abrasive texture; very silty grading to siltstone; moderately calcareous; scattered phosphatic material; no laminations; extremely weak trace cut fluorescence; no visible cut; extremely pale yellow residual cut fluorescence.

6710' LIMESTONE - tan; hard; blocky and angular; dull slightly resinous; cryptocrystalline; silty in places; no bonding; no cut.

6720' SANDSTONE - brown-gray; very fine to fine; subangular to subrounded; moderately well sorted; friable to moderately induration; grain packed; slightly calcareous; quartz and feldspar with scattered lithic fragments and occasional very fine shell fragments; no sample fluorescence; extremely weak cut; residual; no visible.

6730' SANDSTONE - light gray-white; fine to medium; subangular to subrounded; poor sphericity; moderate to moderately well sorted; friable to moderate induration; grain packed with trace kaolinitic cement; quartz with abundant feldspar; scattered lithic fragments; grades to siltstone; occasional sporbo in dark cuttings.

6740' SHALE - medium to dark brown; soft to hard, crunchy; blocky tabular cuttings are prominent; occasional good fissility; some gradational siltstone shale; overall silty appearance; dull to slightly resinous luster; abundant rounded limey blebs occasionally preserved forams; overall sample moderately calcareous; pale green-yellow cut fluorescence; no sample fluorescence.

6750' LIMESTONE - tan, gray; very hard; brittle; crunchy; sharp irregular fracturing; trace very thin laminations; microcrystalline to sucrosic texture; resinous to sparkling luster; trace forams; infrequent sandstone fragments with abundant pyrite nodules on surface; very weak pale yellow residual fluorescence.

6760' SANDSTONE - white, light gray; fine to upper medium grained; angular to occasionally subrounded; moderate sorting; subprismoidal to subspherical; moderately well indurated; abundant calcareous cement; quartz with feldspars; occasional dark lithics; abundant pyrite on smaller cuttings; trace sporbo; siltstone appears arenaceous in places; no sample or cut fluorescence.

6770' SILTSTONE - medium gray, gray-brown; very firm; structureless to slightly fissile; slightly gritty to arenaceous texture; dull earthy luster; occasional cuttings have kaolinite attached; pale orange sample fluorescence; slow streaming green cut fluorescence.

6780' CLAY - light pale gray; thin runny consistency; very abrasive texture due to high angular firm solids content in sample; good solubility, effervesces in acid; no discernible nodules.

6790' LIMESTONE - tan, light gray; very hard and brittle, crunchy; angular to subangular cuttings; no visible laminations; smooth to slightly grainy texture; resinous luster; argillaceous; trace relict forams; trace tarry material on sandstone, spotty orange sample; extremely slow diffuse yellow-green cut fluorescence.

6800' SANDSTONE - white, light gray; fine to medium grained, angular to subrounded; moderately well sorted; subprismoidal to moderately spherical; easily friable; poorly consolidated; quartz with subequal amounts of feldspar, less lithics, occasionally glauconitic; abundant kaolinitic matrix; moderately calcareous; frequently pyrite; readily absorbs water; good apparent porosity; spotty mineral fluorescence; very slow green-yellow cut fluorescence.

6810' CLAY - light gray; slightly more thick, pasty weakly stiff consistency; soft abrasive texture; less soluble; increasing cohesion; slightly calcareous; trace soft gritty nodules; abundant slough; spotty bright yellow-green sample fluorescence; slightly stronger, faster green cut fluorescence.

6820' SILTSTONE - medium to dark gray-brown; slightly soft to very firm; many cuttings very brittle; gradational from shale with irregular fissility; slightly gritty texture; dull earthy luster; few cuttings have orangish-brown attached to fractured edges; very weak green cut fluorescence.

6830' SANDSTONE - white to light gray; fine to medium grained; very sharp, angular to rounded; moderate sorting; subspherical to prismoidal; kaolinitic matrix contains abundant quartz and feldspars; occasional dark brown, gray lithics infrequently glauconite; readily absorbs water; slightly calcareous; very pyritic; mineral fluorescence masks possible sample fluorescence; extremely weak pale yellow-green cut following repeated attempts; pale yellow residual fluorescence.

6840' SHALE - dark brown; hard, brittle; crunchy; incipient to semi-uniform layering; very silty; slightly gritty to arenaceous texture; dull earthy luster sparkling with pinpoint mica flakes; occasional white to buff colored calcareous inclusions abundant orange to white yellow mineral fluorescence; pale green cut fluorescence following repeat cuts.

6850' SILTSTONE - medium to dark gray-brown; soft to very firm; structureless subrounded subdiscoidal fragments to rough blocky tabs; sample is gradational between siltstone and slightly shale; tiny mica inclusions; mineral fluorescence masks possible sample fluorescence; pale yellowish-green cut fluorescence only after repeated attempts.

6860' SANDSTONE - white; fine to medium, grading to very fine and silty; subangular; poor sphericity; moderately well sorted; moderately indurated; slightly friable; grain packed with patchy kaolinite slightly moderately calcareous; poor to occasionally fair apparent porosity; abundant feldspar with quartz; scattered black and pale blue grains; spotty pyrite; black grains are probably carbonaceous material; no sample fluorescence; no cut fluorescence; no crush cut; faint cut when cut twice.

6860' SILTSTONE - medium dark brown; moderately indurated; crumbles when broken; blocky to occasionally tabular with rounded edges; dull luster; finely abrasive texture; moderately calcareous with occasional visible calcareous inclusions; no visible laminations; no sample fluorescence.

6870' SANDSTONE - white, light gray; very fine to medium with slight increase medium; subangular; decreased sorting; moderately sorted; moderately indurated; grained packed; calcareous; tight; feldspar with commonly quartz; slightly decreased lithic fragments; kaolinitic; common subparallel carbonaceous microlaminations and stringers; minor blue-green grains; trace very faint yellow mineral fluorescence; slow, very diffuse transparent very pale yellow cut fluorescence; no visible cut.

6870' SHALE/SILTSTONE - medium dark brown, gray-brown; moderate to moderately well indurated; crumbly to slightly brittle; predominantly blocky with slightly rounded edges; silty with minor shaly partings; calcareous with scattered visible calcareous inclusions; no laminations; no sample fluorescence; very slow pale yellow cut fluorescence.

6880' SHALE - medium dark brown; moderate to occasionally well indurated; crumbly to brittle; platy to tabular; dull earthy to dull satin luster; finely abrasive texture; very silty; fair to good bedding or cleavage lineation; calcareous with common visible inclusions, possibly microfossils; no oil stain or sample fluorescence; slow extremely faint wispy streaming very pale yellow cut fluorescence; dissipates rapidly; no visible cut; extremely faint residual.

6885' SILTSTONE - predominantly brown; oil stain cuttings is grayish and less organic in appearance than predominant sample; moderate induration; dull luster; very slightly calcareous; no lamination or bonding; patchy medium brown oil stain; sticky; instant milky yellow cut; very diffuse; clear; very pale straw visible cut.

6890' SHALE/MUDSTONE - medium brown; moderate to moderately well indurated; tough; blocky; dull luster; finely abrasive texture; silty but becoming less so; increase greenish-brown cuttings with higher clay content; very poor fissility; moderately calcareous; faint trace cut fluorescence.

6895' SANDSTONE - medium brown-gray; very fine to medium; angular to subangular; moderately sorted; moderate induration; calcareous; poor porosity; abundant feldspar; common carbonaceous material; dirty appearance; scattered pyrite; flash cut fluorescence; no visible cut; very faint residual.

6900' SHALE - medium gray-brown, greenish-brown; moderate induration; blocky to tabular with slightly rounded edges; dull earthy luster; finely abrasive texture; silty but less so than above; increase clay component; poor fissility; no laminations; calcareous with scattered microfossils; trace smectite or fluorescent claystone as streaks and thin interbeds; no sample fluorescence.

6910' SHALE - medium brown; moderate induration; crumbly; slightly tough; tabular; dull earthy luster; very finely abrasive to rough gritty texture; silty occasionally grades to sandy mudstone; poor but improved fissility; calcareous; common white inclusions, probably microfossils but too distorted to see; no sample fluorescence; occasionally extremely faint wispy greenish cut fluorescence; diffuse very rapidly; no visible cut.

6920' SHALE - medium gray-brown; firm to hard; crumbly; slightly brittle; tabular becoming slightly sharper; dull luster; abrasive, gritty texture; silty, sandy in places; calcareous with scattered white and tan microinclusions; poor fissility; commonly green-gray waxy claystone; no sample fluorescence; extreme slight trace very faint greenish cut fluorescence; no visible cut; no oil stain; no petroleum odor.

6925' SANDSTONE - white; fine to medium; angular to subangular; moderately well sorted; moderate induration; moderately calcareous grain packed; kaolinitic; abundant feldspar, quartz and scattered lithic; occasional brown carbonaceous material; scattered pyrite.

6930' SHALE - medium dark gray-brown; moderately well indurated; slightly brittle; blocky; earthy; very finely abrasive; calcareous; very poor fissility grades to silty mudstone.

6940' SANDSTONE - white, gray; upper fine to medium; angular to subrounded; moderately sorted; friable, occasionally very tight; crunchy; white calcareous cement; quartz and feldspars dominantly disseminated lithics; infrequent glauconite; easily absorbs water; no oil stain.

6950' SHALE - light to medium gray-brown; moderately indurated; crunchy to brittle; platy cuttings are prominent; overall good internal microlayering; smooth to slightly arenaceous texture gradational between siltstone and shale; dull earthy to sparkling luster where mica inclusions are more abundant; no sample fluorescence; weak pale yellow-green cut fluorescence following repeated cut attempts.

6960' SILTSTONE - light to medium gray; very soft to slightly firm, crumbly; subrounded to rounded medium size cuttings with trace incipient fissility grading to silty shale; gritty punky texture; dull earthy luster; occasionally mica; trace pale green cut fluorescence from darker shale cuttings.

6970' SANDSTONE - white, gray; fine to medium; angular to subangular; moderately well sorted; moderate to low sphericity; easily friable abundant kaolinitic matrix with quartz and feldspars as primary constituents, occasionally dark brown, gray lithics; trace glauconite; bright yellow-white mineral fluorescence; extremely weak pale green cut fluorescence with many repeat cuts.

6980' SHALE - dark gray-brown; moderately indurated; brittle to crumbly; platy tabular cuttings; generally good internal microbedding; occasional cuttings are fractured; common limey blebs; slightly gritty to smooth texture; dull earthy luster.

6990' CLAY - light gray; very thick, stiff consistency; sticky, gritty texture; poor solubility; slightly calcareous; increase soft, slimey nodules with very poor solubility; no sample fluorescence; pale green cut fluorescence at first cut.

7000' SILTSTONE - light to medium gray-brown; soft to very firm; brittle, small subrounded cuttings; punky to slightly arenaceous texture; dull earthy luster; more firm cuttings waxy when gouged; bright white-yellow mineral fluorescence; trace oil in fractures.

7010' SHALE - rich dark brown; crunchy; brittle; moderately well indurated; incipient to subplanar microlayering; slightly more gritty texture; dull earthy luster; frequent subrounded white limey blebs; mica inclusions; very slow weak pale green cut fluorescence; no oil odor; trace oil in shale.

7015' SHALE - dark brown; moderately well indurated; crumbly to very tough; sharp, tabular to blocky with slightly rounded edges; rich earthy luster when developing sparkle when dry; abrasive silty texture; poor subparallel cleavage; slightly calcareous; fairly homogeneous; no distinct laminations or bonding; no sample fluorescence; very slow extremely weak wispy streaming to diffuse; very pale greenish cut fluorescence that dissipates rapidly; no visible cut; no stain; no odor.

7020' SHALE - dark brown, grayish-brown; hard; slightly brittle; tabular to occasionally platy; dull luster with common sparkle when dry; silty; abrasive texture; non to moderately calcareous in places; no cut fluorescence.

7025' SANDSTONE - white; fine to medium; subangular; poor sphericity; moderate to moderately well sorted; friable to moderate induration; slightly calcareous; grain packed, abundant feldspar; quartz with scattered gray occasional blue-green grains; local patchy pyrite; common kaolinitic in places; patchy bright yellow mineral fluorescence; occasionally very weak slow pale yellow wispy streaming cut fluorescence from pinpoint areas; rapidly becomes very diffuse; no visible cut.

7040' SHALE - medium to rich dark brown; fair induration; slightly crumbly; slight gritty texture; dull earthy luster; fair to poor fissility; slightly calcareous; trace relict foram blebs; trace silty material with infrequent fine sand grains; trace sample fluorescence from sandstone chips with calcareous mineral fluorescence also; slight trace weak pale yellow streamer from isolated sandstone chip; very poor weak yellow residual cut fluorescence; very weak yellow, very poor background cut fluorescence from shale fragments.

7050' SHALE - medium to rich brown; tough, hard; well indurated; gritty in part; abundant irregular calcite blebs; very weakly calcareous; lacking sharp angular edges to cuttings; trace rounded fragments; slightly sucrosic texture; dominantly gritty, earthy; trace light gray clay interbeds with bright yellow mineral fluorescence; no oil or cut fluorescence.

7070' SANDSTONE - light gray, white; fine to medium grained; light gray is loose, poorly consolidated; very easily friable; white to more well indurated; moderately well sorted; angular to subangular; subprismoidal to subspherical; abundant matrix material dominantly quartz with subequal amounts of feldspars; occasional dark lithics and glauconite; trace mica; no oil indicators.

7080' SHALE - medium to rich dark brown; firm; brittle; breaks into sharp fragments with platy appearance; silty texture; frequently very rough cuttings; dull earthy luster; occasional mica; trace carbonaceous material; trace relict forams; no oil shows.

7085' SILTSTONE - light gray-brown; slightly firm; crumbly; tough in places; subrounded to rounded cuttings with no visible structure; slightly gritty to arenaceous texture; dull earthy luster; trace tar healed fracture; very weak green cut fluorescence; pale yellow-white residual fluorescence; no oil odor.

7090' CLAY - pale gray; thick, pasty consistency, gummy, very abrasive texture due to abundant sharp hard shale cuttings; good solubility; moderate cohesion; trace soft malleable nodules with very poor solubility; transparent yellow-green cut fluorescence with repeated cuts.

7100' SHALE - medium to dark brown; tough, crunchy; brittle; blocky tabular cuttings are abundant occasionally less structured grading to siltstone; slightly gritty to arenaceous texture; dull earthy luster; scattered mica; occasional limey blebs; weak yellow-green cut fluorescence following repeat cuts.

7110' SILTSTONE - very dark olive brown; very dark brown; moderately indurated; crumbly to tough; predominantly blocky with slightly rounded edges; earthy; very gritty, abrasive texture; grades to minor amounts dark brown silty very fine sandstone; shaly cleavage in places; trace black oval inclusions; non to slightly calcareous; pale yellow cut fluorescence cut twice.

7115' SILTSTONE - very dark brown with occasional greenish-gray; possible interbeds; firm to hard; blocky with rounded edges to tabular and sharp; dull luster, very slight sparkle when dry; gritty abrasive texture; infrequently grading to very fine sandstone; non to very slightly calcareous in places; no apparent laminations; very dark cuttings slightly phosphatic; slightly shaly in part; no sample or cut fluorescence; very faint residual cut fluorescence.

7120' SHALE - dark gray-brown; firm to slightly hard; tabular; dull luster with slight sparkle when dry; very finely abrasive texture; poor stair-stepped cleavage; non to very slightly calcareous; no sample fluorescence; trace very weak diffuse cut fluorescence; no visible cut; very faint yellow residual.

7125' MUDSTONE - trace amounts; pale to medium greenish gray; firm; waxy luster, smooth argillaceous appearance; silty; noncalcareous; patch dark brown sticky oil stain on possible fracture plane; fast wispy streaming pale yellow transparent cut fluorescence; straw to amber visible cut.

7130' SILTSTONE/SHALE - very dark brown, gray-brown; firm to hard; crumbles when broken; tabular; earthy; increasing siltiness with distinct increase in abrasiveness; non to slightly calcareous; no laminations; very poor to infrequently fair subparallel cleavage; extremely slow diffuse cut fluorescence; weak pale green-yellow residual.

7130' SANDSTONE - white, predominantly light gray; very fine to medium with trace loose to medium to coarse quartz; angular to subangular; moderately sorted; well indurated; calcareous cement; grain packed; poor apparent porosity; quartz with common feldspar; trace light brown grains; very trace mica; occurs as thin laminations in shale; generally clay or/and silty near contact with shale; minor yellow mineral fluorescence; extremely faint diffuse cut; pale yellow residual.

7135' SHALE - predominantly dark gray brown, brown; firm to hard; tough to slightly brittle; tabular with generally sharp edges; dull luster with slight sparkle; very abrasive texture; very silty; occasional subparallel fissility; non to slightly calcareous; no sample or cut fluorescence.

7140' SILTSTONE - gray-brown; firm to hard; blocky; slightly rounded; dull luster; gritty; calcareous; occasionally mottled with white calcareous material, possibly fracture fill; trace cut.

7140' LIMESTONE - gray, occasionally tan; hard; thin tabular cuttings; dull slightly resinous luster; microsucrosic texture where fractured or broken; gray cuttings grading to calcarnite; trace oil stain on tan cutting.

7145' LIMESTONE - medium gray-brown; well indurated; brittle; tabular to sharp cuttings; slightly resinous; appears porcelaneous; initial slow reaction with HCl, then becomes very rapid.

7150' SANDSTONE - pinkish red; very fine grading to silt; moderately well sorted; moderately indurated; calcareous; dirty appearance; poor apparent porosity; trace blue-green oval grains; grades to calcarnite; no sample or cut fluorescence.

7160' SANDSTONE - white, medium green; fine to medium; angular to subangular; moderately sorted; friable white kaolinitic sandstone to well indurated tight gray sandstone; calcareous quartz and feldspar with patchy pyrite; no cut fluorescence.

7165' SANDSTONE - gray; very fine to fine, occasionally medium; subangular; poor sphericity; moderately sorted; friable to moderately well indurated; calcareous grain packed; tight to fair apparent porosity; commonly kaolinitic; common loose medium size quartz.

7170' SHALE/SILTSTONE - dark brown; firm to hard; blocky; dull with slight sparkle; gritty texture and appearance; silty grading to very fine sandstone in places; slightly calcareous; moderate fissility in places; no laminations.

7175' SHALE - medium to dark brown; crunchy; moderately well indurated; increased fissility breaks in platy fragments; gritty to slightly arenaceous texture; dull earthy luster; occasionally mica; very pale yellow-white residual fluorescence after first cut; pale yellow-green cut fluorescence following repeated cut attempts.

7180' CLAY - light gray; moderately thick pasty consistency; slightly stiff; sticky abrasive texture; poor cohesion; expands slightly when rehydrated; trace medium size soft gritty nodules; weak pale yellow cut fluorescence.

7190' SANDSTONE - white; fine to medium grained; angular to subangular; moderately well sorted; moderate to low sphericity; few cuttings readily absorbs water; dominant grain packed; occasional abundant kaolinitic matrix; dominantly quartz with feldspar mostly alkali; occasional dark lithics; trace glauconite; abundant pyrite; sample contains extensive LCM; hole still very tight; no oil odor, sheen; no sample fluorescence; no cut fluorescence; weak pale yellow residual fluorescence.

7200' CLAY - medium gray-brown; thick, stiff consistency; gummy, abrasive texture; spongy due to LCM; good solubility; few round, soft, pliable nodules with very poor solubility; weakly calcareous; increase glauconite in sandstone; few with abundant pyrite; shale is very silty; pale yellow-green cut fluorescence with repeated cuts; persistent pale yellow residual cut fluorescence.

7210' SHALE - dark brown; firm to hard; crunchy; tough; blocky to platy cuttings; occasional stair-step fissility; gritty to arenaceous texture; dull earthy luster; trace limey blebs; trace pyritic; weak yellow residual fluorescence.

7215' SAND - white, gray; fine to coarse; very angular and subrounded; poorly sorted; moderate to low sphericity; dominantly quartz and feldspars; dark lithics; occasionally glauconite; LCM in sample; cut fluorescence from pipe dope.

7220' SILTSTONE - medium gray; light gray when dry; firm; rounded cuttings; structureless to exhibiting incipient fissility; slightly gritty texture; dull earthy luster sparkling with occasional mica; slight increase in pyritic sandstone; no sample fluorescence; cuts from very pale yellow residual cut fluorescence.

7225' SANDSTONE - white to light gray; very fine to medium; trace coarse, predominantly fine; subangular; poor to moderate sphericity; friable to moderately well indurated; grain packed; calcareous cement; poor apparent porosity; abundant feldspar to small slightly kaolinitic; quartz and spotty dark gray lithic fragments; bright spotty yellow-white mineral fluorescence; occasionally slow diffuse pale yellow cut fluorescence; no visible cut; no oil stain; no fluorescence pops; pale yellow residual.

7230' SANDSTONE - light gray; fine to coarse; angular to subangular; poor to moderate sphericity; moderately sorted; moderate to moderately well indurated; calcareous cement; tight grain packed; abundant feldspar minor kaolinite; common spotty dark gray grades to possible lithic fragments; fluorescence and cut as above.

7235' SHALE - dark brown; firm to hard; blocky; earthy; abrasive silty texture; slightly calcareous; no laminations; very faint trace cut fluorescence.

7240' SANDSTONE - white to light gray; fine to medium, occasionally coarse; subangular to subrounded; poor to moderate sphericity; moderately sorted; moderately well indurated; common loose sand in sample; grain packed calcareous cement; poor apparent porosity; quartz with abundant feldspar; common medium to coarse subrounded lithic fragments; trace blue-green grains; kaolinitic in places; no visible oil stain; no odor; spotty bright yellow mineral fluorescence; occasional slow wispy streaming pale yellow cut fluorescence; no visible cut; faint residual.

7245' SANDSTONE - white, light gray; fine to coarse; angular to subrounded; moderate sphericity; poor sorting; moderately indurated; grain packed calcareous cement with scattered kaolinite; poor apparent porosity; occasionally fair where coarse grained; quartz with abundant feldspar; spotty dark gray lithics; trace mica; no stain or odor; no blebs; very slow weak very diffuse pale yellow cut fluorescence; no visible cut; very pale yellow residual.

7250' SANDSTONE - white, occasionally light gray; fine to coarse, predominantly fine to medium; angular to subrounded; predominantly subangular; poor sphericity; moderately sorted; moderate induration; increase loose sand; calcareous and kaolinitic cement; grain packed; overall poor apparent porosity; quartz abundant feldspar; minor blue-green grains; decreased lithics; spotty yellow white mineral fluorescence; extremely weak diffuse pale yellow cut fluorescence.

7255' SANDSTONE - white; fine to coarse; subangular to subrounded; poor sphericity; moderately sorted; moderately indurated; abundant loose sand; calcareous; poor to fair apparent porosity; quartz with abundant feldspar; trace rose quartz with minor pale blue-green grains; trace brown mica stain; spotty mineral fluorescence; extremely diffuse cut fluorescence; no visible cut; no fluorescence pops.

7260' SANDSTONE - white; fine to coarse; angular to subangular; poor sphericity; poor to moderately sorted; moderately indurated; grain packed; calcareous cement, occasionally kaolinitic; poor apparent porosity; abundant feldspar, quartz; scattered biotite and lithic fragments; trace orange stain quartz.

7265' SANDSTONE - white; fine to coarse; subangular to rounded; poor to moderate sphericity; poorly sorted; moderately indurated; common loose coarse grains; grain packed; calcareous and kaolinitic cement; quartz with feldspar; scattered subangular lithics; occasional rounded blue-green grains.

7270' SHALE - medium dark brown; firm to hard; tough to slightly brittle; tabular; earthy sparkle; silty abrasive texture; no laminations; no cut fluorescence; very faint residual cut fluorescence.

7275' SANDSTONE - white, light gray with slightly greenish tint; fine to coarse; angular to subrounded; poor sphericity; poor to moderately sorted; moderate to moderately well indurated; grain packed; calcareous cement; poor to occasional fair apparent porosity; abundant feldspar with increased quartz; spotty gray lithic fragments; common pale green-white to blue-green grains; scattered mica flakes; trace mineral fluorescence; no immediate cut fluorescence.

7580' SANDSTONE - common sand; slight increase round sea green grains; trace orange grains; no oil stain; no odor; no fluorescence pops; no sheen; very weak trace diffuse pale yellow cut fluorescence.

7285' SANDSTONE - white with pale bluish tint; fine to coarse; angular to subrounded; poor sphericity; poorly sorted; moderately indurated; good to poor; tight; calcareous; common pale blue-green grains giving blue tint; abundant feldspar common quartz; trace interbedded shale.

7290' SANDSTONE - trace brown, brown-gray; fine; subangular to subrounded; moderately well sorted; friable; moderately indurated; grain packed; slightly calcareous; abundant quartz, minor feldspar; minor sporbo; no sample fluorescence or cut.

7295' SANDSTONE - white; fine to coarse, predominantly medium; subangular to subrounded; poor to moderate sphericity; moderately sorted; moderately indurated; common loose sand; calcareous; common quartz with feldspar; spotty blue-green grains as above; trace pyrite; very weak residual cut.

7295' SHALE - dark brown; firm to hard; crumbly to tough; earthy with common sparkle when dry; silty with gritty textures; non to slightly calcareous; very weak trace diffuse pale yellow cut fluorescence.

7300' SANDSTONE - white; fine to coarse; subangular to subrounded; poor to moderate sphericity; poor to moderately sorted; moderately indurated; grain packed; calcareous cement; abundant feldspar with common quartz; trace bluish grains; spotty copper colored mica; spotty yellow mineral fluorescence; very slow diffuse pale yellow cut fluorescence; no visible cut.

7310' SANDSTONE - white; fine to coarse; angular to subrounded; poor sphericity; poorly sorted; moderate induration; grain packed; calcareous cement; poor to rare moderate apparent porosity; abundant feldspar; quartz with very minor lithic fragments; trace pyrite.

7320' SANDSTONE - white to very light gray; hard; tabular, blocky cuttings; upper fine to upper coarse; angular to rounded; dominantly spherical; calcareous and kaolinitic; tight; grain supported; abundantly quartz; trace pyrite; common brown to black lithic/mafic grains; occasional shale; trace red-pink grains; orange mineral fluorescence; trace very weak yellow-orange residual cut fluorescence only.

7330' SANDSTONE - becoming occasionally carbonaceous; black, pyritic, carbonaceous layering; trace brown oil blebs and sheen in blender; very slow streaming, transparent yellow streaming from carbon cutting; no visible cut; weak yellow-orange residual cut fluorescence.

7340' SHALE - dominantly dark brown; abundantly large, sloughing cutting; firm to hard; small, flaky to large blocky, dominantly structureless cuttings; gritty and silty with possibly very fine disseminated pyrite; no oil or cut fluorescence; trace brown, hard, very argillaceous limestone.

7350' SANDSTONE - white to light gray, develops green tint after acid reaction; hard to occasionally slightly friable; medium lower to coarse upper; dominantly medium upper to coarse lower; angular to subrounded; poor to moderate sphericity; moderately sorted; dominantly calcareous and tight; common kaolinite; abundant white feldspars; clear, vitreous quartz; common dark lithics; occasional pyrite; trace carbon; rare shale clast; yellow to orange mineral fluorescence; no oil or cut fluorescence.

7360' SHALE - increase amounts; dark brown; hard, blocky cuttings; moderately brittle; silty; noncalcareous; pyritic; fish parts; dominantly massive to poorly fissile; rare brown-orange cutting; rare green tuffaceous cutting; trace brown, dolomitic limestone; no oil.

7370' SHALE - dark brown; becoming flaky and increasingly fissile; occasionally slickensides; rare, small siliceous orange-red cutting; trace gray-green, tuffaceous, waxy cutting; occasional brown to off white, dolomitic limestone; sand probably in large part slough.

7380' SHALE - medium dark brown, greenish-brown; firm to slightly brittle; dull earthy luster; silty with abrasive texture; non to very slightly calcareous; no laminations or banding; no sample fluorescence; trace extremely faint yellow residual.

7385' SANDSTONE - gray-green; fine; moderately sorted; friable; clayey matrix; quartz with scattered feldspar and dark grains; fair apparent porosity; no sample or cut.

7395' SHALE - greenish-brown, brown; firm; small, blocky cuttings; very poor fissility predominantly grades to silty mudstone; earthy; gritty; no laminations; noncalcareous; rarely grades to very fine sandstone; no sample fluorescence; trace cut; abundant dope.

7400' SILTSTONE - greenish-brown, gray-green; firm; hard; blocky; dull luster; commonly sparkling when dry; abrasive texture grades to very fine sandstone; non to slightly calcareous; trace carbonaceous material; no sample fluorescence; no cut fluorescence.

7405' SHALE - gray-brown; firm; tabular; dull luster with common sparkle when dry; occasionally appearing sucrosic; non to slightly calcareous; no banding; no sample or cut fluorescence.

7405' SAND - predominantly white sandstone; increasingly coarse; subangular to subrounded grains; common gray opaque quartz grains.

7410' SILTSTONE - greenish-brown to dark brown; firm; crumbly to slightly brittle; tabular to blocky; dull luster with common sparkle; noncalcareous; very poor fissility; some cuttings appear slightly porcelaneous; no sample or cut fluorescence.

7420' SANDSTONE - white, occasionally light gray; fine to coarse; angular to subrounded; predominantly subangular; poor sphericity; moderately sorted; moderately indurated; calcareous; grain packed; poor apparent porosity; quartz with abundant feldspar; common dark gray lithics; trace spotty blue-green grains; faint yellow mineral fluorescence; no visible cut fluorescence.

7430' SANDSTONE - white; fine to coarse; angular to subrounded; predominantly subangular; poor to moderate sphericity; poor to moderately sorted; moderate to moderately well indurated; grain packed; calcareous cement; tight; slightly kaolinitic in places; quartz with abundant feldspar; trace greenish and occasional pale blue grains; trace dark lithic fragments; spotty yellow mineral fluorescence; no cut.

7440' SHALE - gray-brown; firm; tabular to blocky; dull luster; gritty abrasive texture; non to slightly calcareous; grades to silty mudstone.

7450' LIMESTONE - strong trace; very light to medium brown; hard; very angular, blocky cuttings; sparkling to resinous; microcrystalline; argillaceous; dolomitic to slow acid reaction; very silty; massive; no recognizable microfossils; no oil.

7460' SAND - white, clear, black, light green; very fine to medium; angular to subrounded; subspherical; moderately sorted; dominant feldspars and kaolinite; abundant quartz; frequent dark mafics/lithics; possibly in part carbonaceous material; trace pyrite; abundant calcite; no oil or bulk cut fluorescence.

7470' SANDSTONE - white; hard and brittle; very fine to very coarse, increasingly coarse downward; angular to subangular with common rounded to well rounded; poor sorting; calcareous cement; arkosic; abundant white, partially altered feldspars; common clear, light green, orange-red to pink quartz; common grainy quartzite with occasional pyrite overgrowths; scattered biotite; common dark lithics/mafic grains; occasional pyrite aggregates; tight; no oil.

7475' SHALE - medium to dark gray-brown; firm; crumbly; tabular; flat to dull satin luster; very finely abrasive texture; silty in places; non to slightly calcareous; some spotty white oval markings on dry cuttings, possibly bug ghosts; very poor indistinct fissility, better termed mudstone; no sample fluorescence; extremely diffuse faint greenish cut fluorescence; no visible cut; fain green residual cut fluorescence.

7480' SANDSTONE - white, light gray; fine to coarse; subangular to subrounded; poor to moderate sphericity; poor sorting; moderate to well induration; grain packed; calcareous cement; abundant feldspar; scattered quartz; trace dark gray lithics; trace mineral fluorescence; no cut fluorescence.

7485' SHALE - medium to dark gray-brown; moderate induration; crumbly to occasionally very slightly brittle; tabular; dull earthy luster; slightly higher apparent clay content; very finely abrasive texture; non to slightly calcareous; very poor but slightly improved fissility, still predominantly grades to mudstone; occasionally silty grading to very fine sandstone with slight sparkle when dry; no sample fluorescence; extremely slow, extremely faint greenish cut fluorescence; no visible cut.

7490' SAND/SANDSTONE - light gray; fine to very coarse; subangular to subrounded; moderate sphericity; poor sorting; friable to moderately well indurated; common loose coarse grains; grain packed; calcareous cement; poor apparent porosity; quartz with abundant feldspar; spotty dark gray lithics; trace faint spotty yellow mineral fluorescence; no cut fluorescence.

7495' SHALE - medium to dark brown, reddish brown; firm to hard; tabular to blocky with slightly rounded edges; dull earthy luster; slightly sparkly when dry; very finely abrasive; increased apparent clay content; very slightly calcareous in places; no laminations; very poor fissility, grading to mudstone; very diffuse greenish cut fluorescence.

7500' SHALE - gray-brown, brown; firm; blocky to tabular; earthy; smooth to very finely abrasive; silty in part; very poor fissility; grading to mudstone; no sample fluorescence; continued extremely weak greenish cut fluorescence with faint greenish residual cut fluorescence.

7510' SHALE - dark brown, gray-brown; firm to slightly hard; dark cuttings are generally blocky, gray-brown, tabular; crumbly; earthy luster; very finely abrasive; silty, occasionally grading to silty mudstone; some gray-brown fine sandstone with clayey matrix; slightly calcareous; occasional cuttings floculating slightly in HCl; no sample fluorescence; extremely faint greenish cut fluorescence; no visible cut.

7515' SILTSTONE - brown to light brown with occasional green cast; slightly firm; rounded, tabular cuttings; dull to slightly sparkling luster; abrasive texture; commonly sandy; occasional small sandstone pods within siltstone; very calcareous; rarely grades to silty limestone; occasional coarse micas; generally structureless; rare fissility; rarely grades to silty shale; no oil indicators.

7520' SANDSTONE - white with slight green cast; moderately friable; moderately well indurated; fine to commonly very coarse grained, predominantly upper medium; subrounded to subangular; very poorly sorted; predominantly low sphericity; structureless; calcareous cement, quartz, feldspars, light green transparent grains, dark green opaque grains; occasional micas, occasional lithics; occasionally argillaceous; rarely silty; good apparent porosity; no oil indicators.

7525' SHALE - medium brown to dark brown; slightly firm to commonly firm; subrounded to rounded, tabular cuttings; dull to slightly sparkling luster; slightly abrasive texture; common moderate fissility; occasional slickensides; occasional siltstone, sandstone, calcareous inclusions; commonly very calcareous; occasionally finely micaceous; commonly very silty; commonly may be called a shaly siltstone; no oil indicators except very slight weak very pale green-yellow cut fluorescence; very pale yellow residual cut fluorescence.

7540' SHALE - dark gray-brown to brown; hard to very hard; well indurated; very slightly brittle; common large sloughing shale fragments; predominantly medium, subangular to subrounded, slightly blocky to irregular, tabular cuttings; dull to slightly sparkling luster; slightly abrasive/gritty texture; micaceous; very silty; poor fissility; slightly calcareous; trace foraminiferal debris; minor coarse silty streaks and laminations; occasional waxy, clayey, highly slickensided surfaces; no cut fluorescence.

7545' SHALE - persistent trace slickensided surfaces; generally structureless; gritty; silty; increasingly calcareous; persistent foram debris; micaceous; minor black carbonaceous material; no cut fluorescence.

7555' SANDSTONE - white; fine to very coarse; subangular, subrounded; poor sphericity; poor sorting; moderate induration; common loose coarse to very coarse grains; calcareous cement; kaolinitic in part with common to abundant feldspars; scattered dark gray grains with minor mafics; trace mineral fluorescence; rare very weak diffuse pale yellow cut fluorescence.

7555' MUDSTONE - dark brown, very dark gray-brown; firm; blocky; rich earthy luster; slight sparkle when dry; very finely abrasive texture with silty appearance; rare very poor fissility; non to moderately calcareous; occasional visible inclusions, possibly bugs; no sample fluorescence; very weak cut fluorescence, possibly x-pel G contamination.

7560' SANDSTONE - white, light gray; fine to coarse; angular to subangular; poor sphericity; poor to moderate sorting; moderate to moderately well indurated; tight; calcareous cement; more ratty appearance than above with trace mudstone in matrix in occasional cuttings; quartz with common to abundant feldspar; common dark gray grains; possible smokey quartz; trace green and bright pink grains; rare mineral fluorescence; no cut fluorescence.

7570' SANDSTONE - white; fine to coarse, predominantly medium; subangular to subrounded; moderate sphericity; moderate sorting; friable to moderate induration, common loose grains; calcareous cement; poor apparent porosity; abundant feldspars with common gray and white quartz; common but decreased dark gray fragments; kaolinitic in places.

7577' SANDSTONE - light gray, salt and pepper; fine to medium; subangular; poor to moderate sphericity; moderately well sorted; moderately well indurated; tight; calcareous; less feldspar than above.

7580' SANDSTONE - light gray; hard and brittle, occasionally very hard; very fine to coarse; angular to subrounded; dominantly low sphericity; poor sorting; tight; commonly calcareous to kaolinitic; quartz and abundant feldspars; common micas; common gray and green, coarse, rounded quartzitic grains; occasionally pyritic and carbonaceous; scattered dark lithic/mafic grains; rare dark brown, sticky oil stains with dull orange fluorescence; faint milky yellow cut fluorescence and straw visible cut.

7590' SANDSTONE - white and light to medium gray; lower medium to upper very fine grained; subangular to subrounded; poor to moderate sorting; spherical to subdiscoidal; very tight, good calcareous cement; well indurated; low apparent porosity; occasionally parts along subparallel planes; predominantly quartz, common feldspars; abundant biotite; common kaolinitic matrix; trace silty blebs; minor lithic inclusions; slight bright yellow mineral fluorescence; lacking distinct oil fluorescence; weak yellow cut fluorescence probably due to x-pel G.

7600' SHALE - medium to dark brown and gray-brown; hard to very hard; moderate to well indurated; small to predominantly medium, subangular to angular, tabular to slightly blocky cuttings; sparkling to shiny luster; abrasive texture; very micaceous; abundant biotite; weak trace microfossil inclusions; poor fissility; very silty; minor very cherty fragments; slightly calcareous; no oil or cut fluorescence.

7610' CLAY - medium gray to white-gray; soft to slightly stiff; thick, pasty consistency; moderate to good solubility; gritty texture; silty; slightly kaolinitic; sticky; slightly punky; occasionally soft to slightly firm clay nodules; no cut fluorescence.

7620' SANDSTONE - white, light gray and clear; lower fine to lower coarse grained; subangular to medium; spherical to subdiscoidal; poorly sorted; increased abundance of loose quartz grains; persistent tight, well indurated, calcareous sandstone fragments; abundant biotite; occasionally chloritized; trace feldspars; minor kaolinitic matrix; persistent spotty yellow mineral fluorescence; minor yellow residual cut fluorescence (possibly due to x-pel G); lacking good oil indicators.

7630' SHALE - medium to dark brown, occasionally gray-brown; slightly soft to hard; blocky, massive to flaky, weakly fissile; earthy; increasingly soft; silty; slightly punky cuttings grading to claystone; occasionally very hard, calcareous, sparkling, grading to argillaceous limestone; dominantly slightly to moderately calcareous; visible sharp contact with sandstone; abundant x-pel G in blender; weak yellow cuts from contamination; no oil fluorescence; yellow mineral fluorescence from calcareous sandstone; high cuttings gas probably from recirculated carbide.

7640' CLAY - medium to dark gray-brown; increasing amounts thick, moderately stiff; malleable; moderately cohesive to crumbly; dominantly soluble with common poorly soluble, silty claystone cuttings; poorly expansive; moderately calcareous; very silty; no oil.

SHALE - becoming increasingly fissile with occasional small forams, occasional calcite fracture fill, increasing as possible clasts in sandstone.

7650' SANDSTONE - light gray; very hard; fine to medium; angular; poor to moderate sorting; dense and very tight; slightly calcareous; dominantly grain supported with siliceous cement; quartz and feldspars; rarely kaolinitic; abundant lithics; scattered micas; occasionally pyritic; decreased carbon; occasional sharp contact with dark brown shale; shale occasionally as apparent clasts; common moderately bright yellow mineral fluorescence; no stain or cut fluorescence.

7660' SHALE - becoming increasingly medium to dark brown with red tint; slightly soft, rounded, slightly punky cuttings; commonly massive and grading to claystone; increasingly calcareous; silty; scattered small forams; no oil or cut fluorescence; persistent x-pel G contamination.

7670' SANDSTONE - white, clear and light to medium gray; lower very fine to lower medium grained; angular to subrounded grains; poorly sorted; subprismoidal to subdiscoidal; tight; well indurated; strong calcareous cement; commonly brittle; minor kaolinitic clay matrix; low apparent porosity; predominantly quartz with common feldspars; abundant biotite, occasionally chloritized; individual cuttings exhibit shale/sandstone contacts; minor disseminated pyrite; pinpoint spotty pale yellow mineral fluorescence; no cut fluorescence.

7680' SANDSTONE - as above but increasingly kaolinitic and friable; scattered coarse grains; sample predominantly loose grains; 31 units ditch with C-1 through 5, 350 units cuttings gas; common to abundant pinpoint to 2 mm bright yellow to orange-yellow fluorescent pops; weak odor; sample and cut fluorescence largely obscured by bright yellow mineral fluorescence and x-pel G contamination; no visible stain; pops visible as light brown oil.

7690' SHALE - medium red-brown to dark brown, occasionally gray; slightly soft to hard; massive to weakly fissile; dominantly very calcareous; silty; very fine, probably pyritic sparkle; occasionally carbonaceous; occasional scattered, small, calcareous forams; occasionally as apparent clasts in sandstone; no oil or cut fluorescence.

7700' CLAY - light gray; very soft; slightly thick to thin pasty consistency; moderate to very good solubility; slightly creamy; silty; greasy; fluffy; minor soft nodules; no cut fluorescence.

7710' SANDSTONE - white, occasionally clear, and light white-gray; low fine to upper medium grained; subangular to subrounded; spherical to prismoidal; poorly sorted; very tight; well indurated; slightly friable; poor apparent porosity; predominantly quartz, trace feldspars, abundant biotite; minor chlorite stain; strong calcareous cement; minor lithic grains; strong milky yellow cut fluorescence from x-pel G contamination; lacking discernible oil or cut fluorescence.

7720' SHALE - medium to dark brown and chestnut brown; hard; moderate to well indurated; small to medium, subangular to subrounded, slightly tabular to blocky cuttings; dull to slightly sparkling luster; gritty to abrasive texture; silty; calcareous; poor fissility; indistinct microfossil remnants; isolated cuttings exhibit sharp contact with sandstone; no cut fluorescence.

7730' SANDSTONE - white to light white-gray; lower fine to occasionally lower coarse grained; subangular to subrounded grains; spherical to subdiscoidal; poor to moderate sorting; tight; well indurated; slight increase in friability; poor apparent porosity; predominantly quartz; trace feldspar, biotite; minor chlorite staining; calcareous; spotty yellow mineral fluorescence; no cut fluorescence.

7740' SHALE - dark brown to medium to dark chestnut brown; firm to hard; predominantly moderate to well indurated; occasional punky cuttings; small to medium, subrounded, tabular cuttings; slightly dull to sparkling luster; abrasive to gritty texture; silty; poor fissility; calcareous; generally structureless; no cut fluorescence.

7750' LIMESTONE - dark brown; hard and dense; sparkling and subsucrosic; microcrystalline; nonvugular; very argillaceous and silty; slow initial acid reaction, probably dolomitic; no apparent microfossils; associated with dark brown shale; very dull orange mineral fluorescence; no oil.

7760' SHALE - two types: 1) dark brown; hard; angular; slightly hackly cuttings; commonly tabular to flaky; sparkling and silty; noncalcareous; fish debris; fissile; 2) medium brown; slightly soft, rounded, punky cuttings; grades to claystone; massive to slightly flaky; very calcareous; silty; no oil any lith type.

7770' SANDSTONE - light gray; firm to hard; occasionally slightly friable; lower fine to upper medium; angular to subangular; dominantly spherical; poor sorting; calcareous and commonly kaolinitic; arkosic; vitreous quartz; white, commonly altered feldspars; common lithics, chlorite, biotite; dominantly very tight; yellow mineral fluorescence; no oil stain; cut fluorescence from x-pel G.

7775' STRONG TRACE TUFF - gray and light green; slightly soft; waxy; flaky; pyritic; translucent; bright yellow mineral fluorescence; no oil any rock type.

7780' SANDSTONE - becoming commonly medium gray and pyritic; hard and tight; fine to medium; angular; poor sorting; calcareous; arkosic; dull yellow mineral fluorescence; no oil.

7790' SHALE - dark brown; hard, variety, occasionally pyritic, slickensides; rare dark brown, sticky oil stain on slickensided surfaces; milky yellow cut fluorescence.

7790' CLAY - medium brown; soft and cohesive; very soluble; extremely calcareous; silty; slightly sandy; derived from soft brown shales; no pops or iridescence; no petroleum odor.

7800' TUFF - gray; very pale green-yellow; slightly soft, flaky cuttings; waxy and sparkling; translucent; disseminated pyrite; common red, flaky inclusions; bright yellow mineral fluorescence; no oil any lith type.

7810' CLAY - medium to dark gray-brown; soft to slightly stiff; thick, pasty consistency; moderate to good solubility; silty; slightly gritty texture; moderate cohesion; slightly sticky; trace firm, slightly malleable; structureless claystone cuttings; no cut fluorescence.

7820' SANDSTONE - white and light to medium gray; lower fine to upper medium grained; subangular to subrounded; poor to moderate sorting; spherical to subprismoidal; tight; well indurated; low apparent porosity; calcareous; predominantly quartz; trace feldspars, biotite; minor trace glauconitic fragments; some sandstone may represent slough from uphole; minor yellow cut from x-pel G contamination; no discernible oil or cut fluorescence.

7830' SHALE - medium to dark chestnut brown; firm to hard; occasional soft, punky, diatomaceous-like cuttings; predominantly moderately indurated; small to medium, subangular to rounded, tabular cuttings; slightly dull to predominantly sparkling luster; gritty to abrasive texture; poor fissility; very silty; micaceous; trace microfossil remnants; calcareous; minor slickensided surfaces; no cut fluorescence.

7840' SILTSTONE - white and light gray; lower fine to lower medium grained; prismoidal to spherical; subangular to subrounded; poorly sorted; tight; well indurated; low apparent porosity; calcareous; kaolinitic matrix material common; abundant quartz; common feldspars; trace biotite and hornblende; minor glauconitic fragments; no oil or cut fluorescence.

7850' CLAY - medium to dark gray-brown; slightly stiff; thick, pasty consistency; gritty texture; moderate solubility; good cohesion; very silty; very sticky; low to moderate apparent plasticity; trace soft, malleable, structureless claystone cuttings; no cut fluorescence.

7860' SHALE - medium to dark brown; slightly soft to hard; silty to slightly punky texture; sparkling to earthy; slightly to very calcareous; sample overall very calcareous; scattered calcareous inclusions, possibly microfossils; poor to fair fissility; trace slickensides; trace tuffaceous cuttings; no oil.

7870' SANDSTONE - white to light gray; dominantly hard; occasionally slightly friable; very fine to coarse; angular to subangular with occasionally subrounded; moderate sphericity to occasionally subprismoidal; poor sorting; grain supported; slightly calcareous; feldspars, quartz, lithic grains; occasional chlorite; occasional glauconite; trace pyrite; poor apparent porosity and permeability; yellow-orange mineral fluorescence; no oil stain or cut fluorescence; abundant x-pel G.

7880' SANDSTONE - increasingly kaolinitic and friable.

SHALE - medium to dark brown; soft to hard; massive to weakly fissile; occasionally hackly; no apparent fracturing; commonly very calcareous; hard variety slightly calcareous; silty; occasional scattered calcareous forams; no apparent slickensides; no oil or cut fluorescence.

7890' SHALE - medium to dark gray-brown and chestnut brown; slightly firm to hard; moderate to well indurated; small to medium, subangular to subrounded, tabular to slightly blocky cuttings; strong sparkling luster; abrasive to slightly gritty texture; very micaceous; silty; calcareous; abundant x-pel G contamination; no oil or cut fluorescence.

7900' SANDSTONE - white and light gray; lower fine to upper fine grained; subangular to subrounded; subprismoidal to subdiscoidal; tight; well indurated; calcareous; low apparent porosity; kaolinitic matrix; predominantly quartz; abundant feldspar; minor biotite; trace amphibole and pyroxene; minor spotty yellow mineral fluorescence; no oil or cut fluorescence.

7910' CLAY - medium gray to brown-gray; soft; thin to slightly thick, pasty consistency; good solubility; gritty texture; very silty; slightly micaceous; slightly sticky; becoming creamy; minor soft to slightly firm malleable nodules; no cut fluorescence.

7920' SHALE - dark brown; dominantly firm to hard; occasionally slightly soft; platy to flaky cuttings; commonly massive and blocky; overall poor fissility; silty and sparkling; slightly to dominantly very calcareous; very fine disseminated pyrite; scattered red, phosphatic fish parts; no to rare apparent microfossils; trace slickensides; no oil.

7930' SHALE - occasionally gray; slightly soft; tuffaceous; gradational contact with dark brown shale; silty; pyritic; flaky; bright yellow mineral fluorescence; no oil.

7940' CLAY - medium gray-brown to brown; slightly stiff to soft; thick, pasty consistency; slight decrease in solubility; very gritty to slightly abrasive texture; very silty; slightly micaceous; very sticky; good cohesion; common soft, malleable nodules; no cut fluorescence.

7950' SHALE - medium to dark chestnut brown, gray-brown; slightly firm to hard; moderate to well indurated; small to medium, subrounded to subangular cuttings; sparkling luster; finely abrasive texture; slightly calcareous; silty; micaceous; poor fissility; weak trace slickensided surfaces; minor very fine-grained sand pods; trace white calcareous inclusions; no cut fluorescence.

7960' SANDSTONE - white and light gray; upper very fine to lower medium grained; angular to subangular; poorly sorted; prismoidal to subdiscoidal; tight; well indurated; slightly friable; low apparent porosity; calcareous; moderately kaolinitic matrix; predominantly quartz and feldspar; trace hornblende and biotite; minor lithic inclusions; structureless; spotty bright yellow mineral fluorescence; persistent x-pel G contamination; no cut fluorescence.

7970' SHALE - dark gray-brown to brown; firm to hard; moderate to well indurated; occasionally punky to slightly crunchy; small to slightly large; subangular to rounded cuttings; dull to sparkling luster; very finely abrasive texture; very silty; punky cuttings are very clayey; poor fissility; lacking distinct structures; very micaceous; weakly calcareous; minor slickensided surfaces; occasional cuttings exhibit sharp contact with fine to medium-grained, well indurated sandstone; no cut fluorescence.

7980' CLAY - medium gray-brown to slightly dark brown; soft to stiff; thin pasty consistency; moderate to good solubility; gritty texture; very sticky; silty; micaceous; no cut fluorescence.

8000' CLAY - gray-brown to brown; firm and thick; gummy to crumbly; common large rounded aggregates over shakers; soluble with scattered less soluble nodular lumps; moderately calcareous; extremely silty; mild expansion when rehydrated; abundant sporbo; no oil.

8010' SANDSTONE - light gray to white; slightly friable to very firm and brittle; fine lower to coarse lower; angular to subrounded; poor to moderate sorting; tight; kaolinitic; very slightly calcareous; arkosic; feldspars and quartz; trace lithics; pyrite; spotty yellow mineral fluorescence; no cut fluorescence.

8020' SHALE - commonly medium brown to gray-brown; soft, slightly punky, rounded cuttings; earthy; slightly calcareous; slightly silty; occasional glauconite, overall decreased amounts; sporbo; occasional abundant forams; no oil.

8034' Lost circulation in sands from 8006' to 8025'.

8040' Repeated lost circulation, samples 98% LCM.

8060' SHALE - medium to dark gray-brown; slightly mottled appearance; firm and brittle; silty; slightly calcareous; delayed, mild acid reaction; glauconite inclusion; occasional calcareous forams; occasionally pyritic; occasional fish part; no oil.

8070' SANDSTONE - light gray to white; hard to slightly friable; very fine to very coarse; angular; poor sorting; calcareous to kaolinitic; arkosic; clear quartz; common dark gray, blue-gray grains; occasional mica, pyrite; yellow-orange mineral fluorescence from calcareous cuttings; no cut fluorescence; sample 98% LCM; partial returns.

8080' SAND - desilter sample; clear, white; very fine to coarse; angular to subangular; dominantly spherical to subprismatic; clear and cloudy quartz; abundant calcite; trace pyrite aggregates; abundant LCM; no oil.

8105' SANDSTONE - light gray, brownish gray; very fine to medium; commonly silty; subangular; poor to moderate sorting; friable to moderate induration; predominantly grain packed; slightly calcareous; commonly kaolinitic; trace bright green glauconite.

8110' SANDSTONE - medium gray, brownish gray; very fine to medium, predominantly fine; commonly silty; moderately sorted; slightly friable to moderately well indurated; grain packed with common kaolinitic interstitial clay, kaolinite; scattered black mafics; trace green grains, possibly glauconite; clay in matrix; moderately expansive.

8120' SHALE - dark brown; firm to hard; tabular; earthy; calcareous in places; poor to fair fissility; occasional white microinclusions interbedded with silty sandstone; trace slow wispy streaming greenish cut fluorescence.

8130' SHALE - dark brown; hard; blocky; angular; earthy luster; slightly calcareous; very finely abrasive texture; cuttings may be slough.

8140' SANDSTONE - light to medium gray; very fine to medium with trace coarse; very poorly sorted; friable to well indurated; calcareous; grain packed; common gray clay; possibly kaolinite; trace pyrite; becoming increasingly silty; no sample or cut fluorescence.

8150' SILTSTONE - medium gray; soft, clayey cuttings; dull earthy luster; soluble with agitation; moderately expansive where very clayey; noncalcareous; no cut fluorescence.

8160' SHALE - very dark brown; firm to hard; tabular with sharp edges; dull luster, occasionally polished as if sheered; silty in places; trace smectite lenses; calcareous in places with visible microinclusions; trace sporbo; no sample fluorescence; moderately fast wispy bright green-yellow cut fluorescence; no visible cut.

8170' SHALE - dark brown; firm to hard; blocky; dull earthy luster with moderate sparkle when dry; gritty, silty texture; minor sheering with polished surfaces; slightly calcareous; no sample fluorescence; weak wispy streaming greenish yellow cut fluorescence, probably x-pel G contamination; no visible cut.

8180' SANDSTONE - light gray, pale brownish gray; very fine to coarse; subangular; poor sorting; friable to moderately well indurated; grain packed; slightly calcareous; quartz and feldspar with scattered black mafics; common kaolinitic cuttings with trace bright green mica; common gray tuffaceous claystone.

8190' SANDSTONE - pale brownish gray; very fine to fine; subangular; moderately well sorted; friable; calcareous; grain packed; quartz and feldspar with scattered mafics; occasional disseminated pyrite; kaolinitic in places.

8200' SHALE - brown, brown-gray; firm to hard; blocky and massive to tabular, elongated, fissile; gritty and silty; slightly calcareous; occasional fish scale on bedding plane; occasionally finely sandy and grading to siltstone; no oil.

8210' SANDSTONE - light to medium gray, occasionally white; very fine to medium; subangular; poor to moderate sorting; friable to moderate induration; grain packed; slightly calcareous; poor apparent porosity; quartz and feldspar; trace white microfossil inclusions in shale; trace polished surfaces; minor spotty mafics; occasional white kaolinitic cuttings with trace bright green mica; occasional spotty yellow mineral fluorescence; no cut fluorescence.

8215' SANDSTONE - pale brownish gray; fine to medium; angular to subrounded; poor to moderate sphericity; moderately well sorted; friable to moderate induration; grain packed; slightly calcareous; poor to moderate apparent porosity; abundant quartz; spotty kaolinite; spotty mafics; trace very pale green grains; bright yellow mineral fluorescence; very slow weak diffuse to wispy streaming light yellow cut fluorescence; no visible cut; very weak light yellow residual cut fluorescence.

8225' SHALE - dark brown, very dark gray-brown; hard; slightly brittle to very tough; dull satiny luster with common sparkle when dry; silty with very finely abrasive texture; minor polished surfaces; no visible slickensides; moderately calcareous with common microinclusions; no sample fluorescence; slow, weak, wispy streaming greenish yellow cut fluorescence from pinpoint locations; becomes extremely diffuse.

8230' SHALE - very dark brown; hard; blocky with sharp edges; tough to slightly brittle; earthy with common polished surfaces, no distinct slickensides; silty with very finely abrasive texture; calcareous; no sample fluorescence; very weak cut as above.

8235' SANDSTONE - gray-white; very fine to medium; moderately sorted; moderate to moderately well indurated; calcareous; tight; quartz and feldspar with scattered mica; interbedded with shale; patchy yellow mineral fluorescence; infrequent weak cut fluorescence.

8240' SILTSTONE - silver gray; firm; tabular to shaly in appearance with no distinct fissility; submetallic luster; trace disseminated pyrite; no sample or cut fluorescence.

SANDSTONE - pale brown gray; medium; subangular to subrounded; well sorted; moderately well indurated; slightly calcareous; grain packed; fair apparent porosity; abundant quartz; spotty black mafics; moderately bright yellow mineral fluorescence; very diffuse pale greenish cut fluorescence; no visible cut; very pale yellow residual cut fluorescence.

8247' SHALE - medium to dark brown; hard; blocky to tabular, commonly hackly cuttings; resinous/shiny to sparkling; non to occasionally moderately calcareous; silty; pyritic; occasionally carbonaceous; occasional banding; dark brown visible oil staining on slickensides and occasional granular surfaces; no to very dull orange oil fluorescence; instant milky yellow cut fluorescence; straw visible cut; occasional green-yellow cut from brown-gray sandstone.

8255' SHALE - abundant slickensides and polished surfaces; sharp contact with sandstone; sandstone probably as lenses, pods; trace tuffaceous cuttings; trace visible stain on slickensides; streaming milky yellow cut fluorescence; trace glauconite, sporbo.

8260' SANDSTONE - white to medium gray; firm to hard; very fine to coarse; angular; poor sorting; calcareous; commonly kaolinitic; tight; quartz and feldspars; scattered glauconite; trace sporbo; occasional shale clasts; as streaks in shale; mineral fluorescence masks any oil fluorescence; no visible stain; weak yellow cut fluorescence from occasional cuttings; no visible cut.

8270' SHALE - dark brown; firm to hard; blocky to flaky cuttings; dominantly poor fissility; occasional good planar partings; very silty and gritty; sparkling; occasional slickensides and shiny, gouged surfaces; non to moderately calcareous; micromica; occasional very fine disseminated pyrite; trace phosphatic fish parts; rare apparent forams; no stain or oil fluorescence; trace weak yellow cut fluorescence.

SANDSTONE - occasional brown tint, possibly oil; occasional green-yellow sample fluorescence, in part mineral; slow green-yellow cut fluorescence; fair green-yellow residual cut fluorescence; no visible cut; no pops, odor.

8280' TUFF - strong trace; medium gray; slightly firm; flaky to blocky; waxy and translucent on thin edges; occasionally silty and abrasive grading to tuffaceous siltstone; altered and bentonitic; bright yellow mineral fluorescence; no oil; fair green-yellow cuts from shale and occasional sandstone.

8310' SANDSTONE - light gray with common very light brown, oily tint; firm to friable; fine to medium; angular to subangular; moderate sphericity; moderate sorting; slightly calcareous; kaolinitic; fair to good apparent porosity in friable cuttings; quartz; scattered green glauconitic grains; trace micas; scattered black, mafic/lithic grains; even bright yellow sample fluorescence; fast streaming to blooming, bright yellow to green-yellow to blue-white crush cut fluorescence; strong green-yellow residual cut fluorescence; pale straw visible cut; weak odor from blender; no pops; very abundant LCM.

8330' SHALE - dark brown; hard; flaky to blocky, commonly elongated cuttings; sparkling; occasionally shiny and gouged; silty; noncalcareous to possible dolomitic; gritty; micromica; disseminated pyrite; fish parts; decreased occurrence slickensides; occasional sticky brown oil stain on slickensides and rare calcite coated fracture; instant milky yellow cut fluorescence; dark straw visible cut.

8340' SANDSTONE - light gray; commonly apparently saturated with very light brown oil; firm to friable; fine to medium; subangular; moderate sorting; slightly calcareous; kaolinitic; clear quartz and feldspars; occasional bright to dark green glauconite grains; trace gray quartzite, black mafic/lithic grains; rare rose quartz; trace mica; occasional shale streak or clast; bright yellow to yellow-green sample fluorescence; good green-yellow crush cut fluorescence; pale straw visible cut.

8350' SHALE - dark brown; hard; hackly; sparkling; very silty; non to moderately calcareous; micromica; probably very fine disseminated pyrite; poor fissility; very rare heavy oil stain; dominantly no sample or cut fluorescence; fair to good crush cuts from sandstone.

8400' SILTSTONE - trace amounts; gray; hard; pyritic and carbonaceous; moderately calcareous; trace brown oil staining; weak green-yellow cut fluorescence.

LIMESTONE - good trace; light gray-brown; hard and very brittle; small, angular cuttings; translucent on thin edges; micritic; trace red, black grains; no oil or cut fluorescence.

8410' LIMESTONE - light brown; hard; dense; micritic; very fine, angular sand exposed by acid; no oil.

SHALE - dark brown; hard; silty and sparkling; non to moderately calcareous; disseminated pyrite; rare sporbo; trace slickensides; no oil.

SANDSTONE - becoming commonly medium gray; hard; calcareous; pyritic; yellow mineral fluorescence; no to very weak green-yellow cut fluorescence.

8430' SANDSTONE - white, gray; fine to medium; angular to subangular; moderately sorted; very low to moderate sphericity; dominantly loosely consolidated; very easily friable; occasionally well indurated; quartz with dark lithics; minor feldspars; common kaolinitic matrix; well indurated cuttings contain calcareous cement; yellow-orange sample fluorescence; very slow transparent green cut fluorescence; light yellow-white residual cut fluorescence; no petroleum odor.

8440' SHALE - medium to very dark brown; hard to firm; moderately well indurated overall; incipient to well defined fissility; blocky to tabular; silty to slightly arenaceous texture; dull earthy to sparkly luster when more mica is present as inclusions; hard cuttings are waxy when gouged; slightly to moderately calcareous; mineral fluorescence masks possible sample fluorescence; very slightly transparent green cut fluorescence; pale yellow-green residual cut fluorescence.

8450' CLAY - light gray-green; thick, very stiff consistency; gummy, gritty texture; poor solubility; slightly calcareous; medium to large, malleable, slimy nodules with very poor solubility; sample fluorescence is indiscernible; no cut fluorescence; light yellow-green residual cut fluorescence.

8460' SAND - clear, white, gray; very fine to coarse; angular to subrounded; very poorly sorted; moderate to low sphericity; unconsolidated; dominantly quartz with feldspars and lessor amounts of lithic fragments; trace limestone; bright yellow, yellow-green mineral fluorescence masks sample fluorescence; no cut fluorescence; very pale yellow residual fluorescence.

8470' LIMESTONE - dark brown; hard, brittle; crunchy; irregular, sharp, hackly fracture; no visible laminations; sucrosic to very rarely microcrystalline texture; sparkling luster; very argillaceous; trace carbonaceous material.

8480' SHALE - dark brown; slightly soft to hard; dominantly well indurated; angular to subangular, blocky cuttings; incipient to moderate fissility; slightly to moderately calcareous; trace mica; dull luster; occasionally waxy when gouged; slightly to moderately calcareous; no oil odor or sheen; no sample fluorescence; very slow yellow-green cut fluorescence; no residual cut fluorescence.

8490' CLAY - light gray; thick, stiff, pasty consistency; sticky, abrasive texture; poor solubility; slightly calcareous; small to medium, firm, malleable nodules with very poor solubility to insoluble grading to claystone; trace sandstone with abundant pyrite nodules; mineral fluorescence masks any sample fluorescence; slightly faster yellow-green cut fluorescence from sandstone; pale yellow residual cut fluorescence.

8500' LIMESTONE - white, brown, gray; moderately soft to hard; blocky to tabular cuttings; commonly massive; commonly drusy and silty; 5% mafic inclusions; micromica; no oil or cut fluorescence.

8510' SHALE - dark brown; slightly soft to hard; blocky to tabular cuttings; poor fissility; commonly massive; commonly gritty and silty to slightly arenaceous; occasionally earthy, soft, rounded, massive, grading to claystone; dominantly very calcareous, occasionally noncalcareous; micromica; occasional very fine disseminated pyrite; rare trace slickensides; trace possible calcite veinlet; associated light brown limestone; no oil or cut fluorescence.

8520' SHALE - dark brown; soft to firm; tabular to rounded cuttings; commonly massive; commonly gritty and silty; slightly less calcareous than above; rare slickensides and polish; trace yellow moderate sample fluorescence; weak yellow-green cut fluorescence; weak yellow residual cut.

8530' CLAY - medium brown-gray; soft; smooth and nonnodular; slightly malleable and cohesive; very soluble with occasional less soluble lumps; nonexpansive; extremely calcareous and silty; abundant very fine sand; no petroleum odor, iridescence, fluorescent pops; no odor or oil from blender.

8536' SANDSTONE - light gray; hard; fine to medium grained; angular; poorly sorted; irregular texture; calcareous and occasionally noncalcareous; grain supported; rare mafics; arkosic; clear quartz, milky white feldspars, opaque mafics; yellow cut sample fluorescence; no odor; pale yellow sample fluorescence.

8545' SHALE - mottled brown to gray; hard; jagged pieces; calcareous; cement; extremely silty; nonfissile; micromica; rare sporbo; rare pyrite; rare sandstone; weak pale yellow sample fluorescence; moderately strong green-yellow cut fluorescence.

8550' LIMESTONE - black to gray; hard; microcrystalline; calcareous cement; argillaceous; rare pyrite; no oil.

SANDSTONE - gray; hard; fine to coarse grains; angular to subrounded; poorly sorted; calcareous cement; no oil.

8560' SANDSTONE - white, gray; fine to coarse; angular to subrounded; poorly sorted; moderate to very low sphericity; dominantly easily friable, occasionally well indurated; quartz, feldspars, scattered dark lithics; infrequent glauconite; few cuttings are extensively pyritized; trace kaolinite; trace yellow-orange sample fluorescence; slow light yellow-green cut fluorescence; light yellow translucent residual cut fluorescence.

8570' SHALE - dark brown; firm to hard; angular to subangular, blocky to tabular; incipient to fair fissility; slightly calcareous; silty to arenaceous texture; sparkling luster with scattered mica inclusions; trace carbonaceous material; weak yellow-orange sample fluorescence; slow streaming milky yellow-green cut fluorescence; light yellow residual cut fluorescence.

8580' CLAY - light gray; thick, very stiff consistency; gummy abrasive texture due to hard, angular cuttings; poorly soluble; abundant small, rounded, soft, slimy, malleable nodules with very poor solubility; slightly calcareous; weak slow green cut fluorescence from organic shale; light yellow residual cut fluorescence; no oil odor.

8590' SAND - clear, white, gray; fine to coarse; angular to rounded; poor sorting; moderate to low sphericity; dominantly unconsolidated quartz; minor feldspars, occasional glauconite; trace limestone; abundant mineral fluorescence from claystone; very slow green cut fluorescence; light yellow residual fluorescence.

8600' SHALE - dark brown; hard; well indurated; trace interlayered with sandstone; silty to slightly arenaceous texture; dull luster; occasional mica; slightly to noncalcareous; subangular to angular, blocky cuttings; no sample fluorescence; very slow streaming yellow-green cut fluorescence; pale yellow residual cut fluorescence.

8610' SILTSTONE - light green-gray; soft to slightly firm; structureless, rounded cuttings; moderate to noncalcareous; slightly gritty texture; dull earthy luster; occasional mafics; trace orange-brown sample fluorescence; slow milky green-yellow cut fluorescence; very pale yellow residual cut fluorescence.

8620' CLAY - medium gray; stiff; very thick consistency; soft gummy texture; good cohesion; slightly calcareous; small rounded, soft slimey nodules with very poor solubility to insoluble; weak orange-brown sample fluorescence; green-yellow cut fluorescence.

8630' SHALE - gray to black; hard to firm; coarse to very fine; tabular; subangular to subrounded; earthy; noncalcareous and calcareous cement; nonfissile; massive shale; rare pyrite; sharp contact between shale and sandstone; very weak light yellow cut sample fluorescence.

8645' SANDSTONE - light gray; hard; very coarse to fine; tabular; angular; calcareous cement; low porosity; arkosic; quartz and feldspar and mafic within rock finer grain; no odor; weak pale yellow cut sample fluorescence; pale yellow mineral fluorescence.

8650' SHALE - brown to black; firm to hard; large to small, tabular; earthy; angular; commonly massive; calcareous and noncalcareous cement; nonfissile; calcite veining; no odor.

8660' SHALE - brown or black; soft to hard; large to very small; earthy, calcareous cement; commonly massive; slickensides; no oil; abundant glauconite.

8680' SANDSTONE - white to brown; hard; fine to medium; prismoidal to subdiscoidal; medium well sorted; hackly; glassy; calcareous cement; massive; rare forams; arkosic; quartz; feldspars; mafics; no odor; sample fluorescence is weak pale yellow; no odor.

8690' SHALE - medium brown to dark brown, gray; soft to hard; large cut; irregular; hackly; silty texture; dull; calcareous; contact with sandstone; low porosity; commonly massive; commonly nonfissile; no sample fluorescence.

8700' SANDSTONE - medium brown to dark brown; dominantly hard; fine grained; subdiscoidal; smaller cuttings; moderately well sorted; glassy; calcareous cement; massive; arkosic; quartz, feldspar, mafic; no sample fluorescence; occasional abundant mica.

8740' CLAY - light gray; moderately thick consistency; soft, lumpy texture; poor solubility; very weakly calcareous; abundant medium to large firm, pliable greasy insoluble to very poorly soluble nodules grading to claystone; no discernible oil shows due to abundant LCM from partial lost circulation.

8750' SANDSTONE - light gray; fine to coarse; angular to rounded; poorly sorted; moderate to very low sphericity; crunchy; moderately well indurated; quartz with abundant gray feldspars and dark lithics; occasional glauconite; trace shell fragments; calcareous cement; most cuttings are grain supported; abundant LCM; patchy bright white mineral fluorescence from claystone masks sample fluorescence; very slow streaming yellow cut fluorescence from sandstone; weak yellow-green residual cut fluorescence.

8760' SHALE - dark brown; firm to hard; brittle; angular to subangular, tabular cuttings; infrequently blocky; no visible internal microlayering; silty to grainy texture; scattered mica inclusions yielding a sparkling luster; slightly to moderately calcareous; few fragments contain trace amounts of carbonaceous inclusions; sample still contains extensive LCM contamination; mineral fluorescence masks possible sample fluorescence; no cut fluorescence; pale yellow-white residual cut fluorescence.

8770' SAND - white, clear; very fine to coarse grained; angular to subangular; poorly sorted; moderate to very low sphericity; dominantly unconsolidated quartz, occasional feldspars and dark lithics; different apparent source area than sandstone fragments; abundant mica from LCM; sample still predominantly LCM; desilter contains markedly less free sand; no discernible sample fluorescence; no bulk cut fluorescence; pale yellow residual cut fluorescence; sandstone fragments give occasional very slow streaming yellow cut fluorescence.

8780' SILTSTONE - light gray-green; soft to slightly firm; rounded subdiscoidal; dominantly structureless; occasional cuttings break in uneven layers; slightly gritty to rarely punky texture grading to silty claystone; dull luster; weakly calcareous; scattered mafics; weak yellow-orange sample fluorescence from sandstone; slow streaming yellow cut fluorescence; milky yellow-green residual cut fluorescence; shale gives slow green-yellow cut fluorescence with pale yellow residual cut fluorescence.

8790' SHALE - dark brown; firm to hard; overall well indurated; angular to subrounded, blocky to tabular with one cutting exhibiting microlayering with fine-grained sandstone; calcareous; silty texture; infrequently arenaceous; dull luster frequently sparkling with pinpoint mica inclusions; still extensive LCM contamination; up to 90% of sample; no petroleum odor, pops, or sheen.

8810' SHALE - medium to very dark brown; soft to hard; hackly to slightly punky; granular to gritty and sparkling; dominantly moderately calcareous; occasionally non or extremely calcareous; very silty; occasional calcite as veinlet or fracture coating; common sporbo; trace slicks and polished surfaces; poor fissility overall; no sample fluorescence; weak gray cut fluorescence; petroleum odor from blender.

8850' SAND - clear, white, green, gray; fine to very coarse; very angular to rounded; poorly sorted; very low to moderate sphericity; unconsolidated; quartz with feldspars and abundant glauconite; difference apparent source area than sandstone fragments; trace free calcite; increase of sandstone with abundant kaolinitic matrix; occasional cuts with parallel mica inclusions; very weak orange-yellow sample fluorescence; no visible cut; very slow streaming light yellow cut fluorescence; light yellow residual cut fluorescence.

8860' SHALE - dark brown; firm to hard; angular cuttings; blocky to thin tabs; slightly calcareous; gritty to rarely arenaceous; dull luster; frequent mica inclusions; still abundant free glauconite in sample; shale has no sample fluorescence; slow transparent green-yellow cut fluorescence; bright yellow-green cut fluorescence; sandstone gives persistent slow weakly streaming light yellow-white cut fluorescence with light yellow residual cut fluorescence.

8870' SANDSTONE - white, light gray; very fine to coarse; angular to rounded, poorly sorted; moderate to low sphericity; more loosely consolidated; quartz with occasional feldspars and lithics; frequent mica inclusions; bright yellow-white sample fluorescence; fast milky yellow cut fluorescence; light yellow residual fluorescence.

8880' SAND - white, clear, green; very fine to very coarse; angular to rounded; very poor sorting; subspherical to prismoidal; dominantly unconsolidated quartz with scattered glauconite and dark lithics; abundant mica from mud additive; no pops or odor; bright yellow-white sample fluorescence; spotty mineral fluorescence; bright milky yellow cut fluorescence; pale yellow-white residual fluorescence.

8900' CLAYSTONE - trace amounts; light gray; soft, easily malleable; sticky; grades from clay; small to large; slightly calcareous; smooth to punky texture; dull earthy luster; expands slightly when hydrated; same bright yellow-white sample fluorescence from sandstone; fast to instant yellow-white cut fluorescence; pale yellow-green residual cut fluorescence.

8910' SANDSTONE - white to light gray to light brown; well indurated; blocky to spherical; subangular to subrounded; well sorted; vitreous luster; calcareous; kaolinite matrix; grain supported; commonly massive; apparent permeability; mostly clear to milky quartz; slightly glauconitic; slight mafics; milky yellow cut fluorescence.

8925' SANDSTONE - white, light gray; very fine to coarse; angular to subangular; poor sphericity; poor sorting; friable to moderately indurated; calcareous cement; grain packed; poor to occasionally fair apparent porosity; predominantly quartz with common feldspar; kaolinitic in places; minor spotty pinpoint mafics; bright white yellow mineral/sample fluorescence; slow diffuse pale yellow-white cut fluorescence; no visible cut.

8935' SANDSTONE - as above; increasingly kaolinitic cuttings; trace gray lithics; no pale brown staining; even bright yellow-white mineral/sample fluorescence; slow wispy streaming yellow-white cut fluorescence; slight increase in yellow with crushing; extremely faint straw visible cut.

8945' SANDSTONE - white to gray with few brown oil stains; poorly indurated; medium to fine; subangular to subrounded; poor sphericity; poor sorting; grain supported; good apparent permeability; calcareous; kaolinitic matrix; mostly quartz; slight mafics; sample fluorescence is moderately scattered.

8950' SANDSTONE - light gray-white; fine to very coarse; angular to subrounded; poor sphericity; poor to locally well sorted; friable to moderate induration; grain packed; calcareous; poor to fair apparent porosity; abundant quartz with common feldspar; patchy kaolinite; trace pale green grains; locally common brown siltstone-shale lith clasts; overall increase in darker grains; some with salt and pepper appearance; patchy to even bright yellow sample fluorescence; slow diffuse pale yellow cut fluorescence; slight intensity increase with crushing.

8970' SANDSTONE - light gray with slightly increased gray grains, giving a slightly salt and pepper appearance; fine to coarse; predominantly medium; subangular to subrounded; poor sphericity; poor to locally well sorted; friable to moderately indurated; grain packed; calcareous; generally poor to moderate apparent porosity; commonly coarse with increase in feldspar; locally kaolinitic; trace medium green grains; even bright yellow mineral/sample fluorescence; slow wispy streaming pale yellow cut fluorescence; very faint straw visible cut with bulk sample; moderately bright yellow-white to greenish yellow residual cut fluorescence; no stain or odor.

8980' SANDSTONE - white; very fine to coarse; very angular to rounded; very poorly sorted; subspherical to prismoidal; dominantly easily friable; occasionally moderately well indurated; quartz and feldspars, occasional lithics; increased abundance of kaolinitic matrix; strong reaction to HCl; trace glauconite; no live pops or fluorescent pops; slightly gassy odor; bright white-green-yellow sample fluorescence; milky yellow cut fluorescence is very slow; light yellow-green residual cut fluorescence.

8990' SANDSTONE - white, light gray; fine to medium; angular to subangular; moderate sorting; moderate sphericity; trace prismoidal; fair to poor induration; grain supported; moderate to good apparent porosity; dominantly quartz with lessor feldspars, trace dark lithics.

9000' SHALE - dark brown; firm to hard; blocky to few tabular fragments; silty to occasionally arenaceous texture; earthy luster; weakly calcareous in places; trace limey blebs.

9010' CLAY - light gray; slightly thick consistency; soft; gritty texture with abundant small sandstone fragments; good solubility; very weakly calcareous; medium to very large greasy to chalky nodules with very poor solubility.

9020' SANDSTONE - white; fine to medium grained; angular to rounded; moderately well sorted; moderate sphericity; loosely consolidated; grain packed; trace kaolinitic matrix/cement; slightly to moderately calcareous; quartz with trace feldspars; glauconite in few cuttings; bright white-yellow sample and cut fluorescence; bright white-green to yellow-green residual cut fluorescence.

9040' SHALE - dark brown; hard to firm; fair induration; gritty texture; dull to slightly sparkling luster when trace mica is present; disappearing off white limey blebs; one cutting with carbonaceous inclusions; weakly to noncalcareous; persistent white-yellow sample fluorescence; milky yellow-green cut fluorescence; bright yellow-green residual cut fluorescence.

9050' SILTSTONE - trace amounts; light gray-brown; soft to occasionally firm; small to medium subrounded and structureless to subangular tabs; slightly gritty texture; dull earthy luster; trace mica; frequent dark heavy inclusions; very slightly calcareous.

9060' SANDSTONE - grayish white; fine to medium; angular to subrounded; moderate sorting; low to moderate sphericity; easily friable to moderately well indurated; quartz; feldspars; very minor dark to light lithics; weakly calcareous; grain supported with trace cement; moderately bright white-yellow sample fluorescence; very weak greenish white cut fluorescence; pale greenish yellow residual cut.

9090' SANDSTONE - gray-white; fine to medium; subangular to subrounded; poor to moderate sphericity; moderately well sorted; friable to moderate induration; grain packed; slightly calcareous; moderate apparent porosity; quartz and feldspar; minor spotty lithic fragments and occasional greenish grains; overall clean appearance; locally pinpoint kaolinite; even bright white-yellow sample fluorescence; fast extremely diffuse to transparent pale yellow cut fluorescence; no visible cut; no fluorescent pops or petroleum odor.

9105' SANDSTONE - gray-white; fine to medium with increased medium; subangular to subrounded; poor to moderate sphericity; moderately well sorted; slightly friable to moderate induration; locally increased calcite cement; predominantly spotty cement; grain packed with poor to fair apparent porosity; predominantly quartz with spotty feldspar; spotty fine grained mafics with slightly increased sea green grains, possibly glauconite; no visible oil stain; even moderately bright white-yellow sample fluorescence; slow extremely diffuse pale yellow cut fluorescence; no distinct increase in intensity when crushed; no visible cut; pale green-yellow residual cut.

9115' SANDSTONE - pale gray-white; fine to medium, predominantly fine; subangular to occasionally rounded; poor to moderate sphericity; moderately well sorted; friable to moderately indurated; grain packed; slightly calcareous; fair apparent porosity; abundant quartz with spotty interstitial kaolinite; spotty gray, brown and sea-green grains; patchy moderately bright white-yellow sample fluorescence.

9120' SANDSTONE - white to light gray; fine to medium; angular to subrounded; moderate sorting; moderate sphericity; grain supported; kaolinitic cement; moderate induration; quartz, occasional feldspars and lithics; trace glauconite; spotty green-white sample fluorescence; very slow milky green-yellow cut fluorescence; light yellow residual cut fluorescence.

9130' SHALE - becoming harder; dominantly dark brown; silty texture; dull luster; waxy when gouged; slightly to noncalcareous; abundant slough; sand still decreasing; trace bright white-green to yellow-white sample fluorescence; yellow-green cut fluorescence with frequent streamers from sandstone.

9145' SANDSTONE - brown, gray-brown; fine to medium with argillaceous matrix; grades from sandy siltstone with argillaceous matrix to argillaceous sandstone with interstitial silt and clay; moderately well indurated; tight; very slightly calcareous where increasingly argillaceous; no bedding lineation; minor glauconite spheroids in some cuttings.

9155' SANDSTONE - white to light gray; fine to medium; subangular to subrounded; poor to moderate sphericity; moderately well sorted; moderate to moderately well indurated; grain supported; spotty calcareous cement; poor apparent porosity; predominantly quartz; locally spotty kaolinite; common kaolinitic bit gouge in sample; moderately bright white-yellow to green-yellow sample fluorescence; very slow very weak diffuse pale yellow cut fluorescence; no visible cut; moderate greenish yellow residual cut fluorescence; no stain or odor.

9165' CLAY - medium gray; moderately thin pasty consistency; easily soluble; moderate cohesion; poor to moderate plasticity; nonnodular; no oil sheen or odor; no pops.

9180' SANDSTONE - brown; moderate induration; medium to silt sized grains; angular to subangular; poorly sorted; arenaceous; quartz; feldspar; lithic fragments; calcareous; poor apparent permeability; moderate intensity; weak pale yellow cut fluorescence.

9190' SILTSTONE - brown, gray-brown; firm to hard; tough to slightly brittle; earthy luster with shaly appearance; abrasive texture; locally arenaceous; grades to mudstone and very fine silty sandstone; very slightly calcareous; no sample fluorescence; extremely faint extremely weak trace greenish cut fluorescence.

9200' SILTSTONE - brown to light gray; soft to hard; finely abrasive texture; earthy luster; calcareous mineralization; occasionally argillaceous; quartz; feldspars; calcareous inclusions; trace very weak intensity yellow cut fluorescence; very weak very pale yellow residual cut fluorescence.

9210' SHALE - dark brown to gray-brown; hard; well indurated; small to occasionally large, angular to subangular, tabular to slightly blocky cuttings; slightly sparkling luster; gritty to very grainy texture; generally siliceous; common white, calcareous inclusions; very silty; slightly micaceous; poor fissility; common fine-grained streaks; weak trace limestone fragments; minor trace spotty yellow sample fluorescence; weak, slow, diffuse green-yellow cut fluorescence.

9220' SAND AND SANDSTONE - white and medium gray; lower fine to upper medium grained; spherical to subprismoidal; poor to moderate sorting; tight; moderate to well indurated; occasionally slightly friable; common loose, clear quartz grains; predominantly quartz; abundant lithic grains; trace heavy minerals; weak calcareous cement; low apparent porosity; weak trace spotty yellow sample fluorescence; slow, diffuse transparent green-yellow cut fluorescence; lacking significant petroleum odor; no live oil pops or oil sheen.

9230' SILTSTONE - medium to very dark brown to gray-brown; firm to predominantly hard; well indurated; small to medium, angular to subrounded, tabular to slightly blocky cuttings; moderate to strong sparkling luster; gritty to grainy texture; silty; micaceous; commonly grades to very silty shale; occasional very fine-grained sandstone streaks and pods; minor trace pale yellow to yellow-green sample fluorescence.

9240' SHALE - medium to dark gray-brown; hard; occasionally soft, punky mudstone; small to medium, subangular, tabular to slightly blocky cuttings; sparkling luster; gritty to grainy texture; very silty; common very fine-grained sand streaks; poor fissility; common calcareous inclusions; micaceous; poor trace green-yellow sample fluorescence; weak diffuse green-yellow cut fluorescence.

9250' SAND - white, clear and light gray; fine to occasionally lower coarse; subangular to rounded; spherical to discoidal; poor sorting; loose; commonly tight; predominantly quartz; trace lithics and heavy minerals; sandstone cuttings have weak calcareous cement; very weak yellow sample fluorescence; slow diffuse green-yellow cut fluorescence; very pale powdery yellow residual cut fluorescence.

9260' SILTSTONE - medium to dark gray-brown and brown; firm to hard; moderate to well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling luster; grainy texture; poor fissility; very micaceous; common calcareous inclusions; commonly grades to very silty shale; indistinct green-yellow sample fluorescence; very weak diffuse green-yellow cut fluorescence.

9270' SAND - clear, white, light gray; lower fine to upper medium grained; subangular to increasingly rounded; spherical to subdiscoidal; poorly sorted; predominantly loose; occasionally hard, tight, well indurated, slightly calcareous sandstone cuttings; predominantly quartz; common lithics; slight trace micas; trace heavy minerals; weak trace pale green-yellow cut fluorescence; slow, indistinct, diffuse, translucent green-yellow cut fluorescence.

9280' SHALE - dark brown to medium gray-brown; slightly firm to predominantly hard; moderate to well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling luster; gritty to grainy texture; micaceous; common calcareous inclusions; poor fissility; occasional soft, punky mudstone; very weak trace green-yellow sample fluorescence; very slow diffuse, transparent to translucent green-yellow cut fluorescence; no live oil pops.

9290' SILTSTONE - brown to gray-brown; hard; angular to subrounded; dull luster with occasional mica sparkles; homogeneous; grain supported; poorly sorted; quartz, dark lithic fragments; no sample fluorescence; no cut fluorescence; very weak very pale yellow residual cut fluorescence.

9300' MUDSTONE - olive brown; soft to slightly firm; tabular to blocky with rounded edges; flat earthy luster; slightly waxy when scored; silty grading to siltstone; hydrates and expands rapidly in 10% HCl with a floculated appearance and minor effervescence; slightly expansive in pure water; trace glauconite; no sample or cut fluorescence.

9310' SILTSTONE - brown; well indurated; homogeneous texture; earthy luster; poor apparent permeability; commonly slightly calcareous; quartz, feldspar, lithic fragments; no pops; very slow, very weak green-yellow cut fluorescence.

9320' SILTSTONE _ brown to light brown; moderately well indurated; homogeneous texture; dull luster; poor apparent porosity; noncalcareous; quartz, mica, lithic fragments; very slow, very weak green-yellow cut fluorescence; very weak green-yellow residual fluorescence.

9325' MUDSTONE - dark red-brown; hard; slightly brittle; thin sharp platy to hackly cuttings; subresinous; slightly translucent luster; smooth to microsucrosic texture; micritic; grading to argillaceous limestone; extremely slow very weak pale yellow cut fluorescence; very weak very pale yellow residual fluorescence.

9340' SAND - white, clear, light gray; lower medium to lower coarse grained; subrounded; well indurated; spherical to discoidal; poor to moderate sorting; loose; predominantly clear quartz, trace lithics and heavy minerals; weak trace mica inclusions; trace well indurated sandstone; very weak green-yellow sample fluorescence; indistinct slow diffuse green-yellow cut fluorescence.

9350' SHALE - medium to dark brown and gray-brown; firm to hard; moderate to well indurated; small to medium, subangular to subrounded, tabular cuttings; sparkling luster; gritty to grainy texture; slightly micaceous; very silty; poor to moderate fissility; common calcareous inclusions; grades to mudstone; very weak green-yellow sample fluorescence.

9360' SANDSTONE - brown; fine to medium grained; angular to subangular; moderate sorting; moderate to low sphericity; fair to poor induration; slightly calcareous; silica cement; dominantly quartz with lessor amounts of feldspars; trace glauconite and mica; trace micaceous claystone; very weak trace yellow-green sample fluorescence; extremely slow translucent yellow-green cut fluorescence; pale yellow-green residual cut fluorescence; no odor, pops or sheen.

9370' SILTSTONE - light to medium gray-brown; soft to slightly firm; small to medium subrounded cuttings; structureless; slightly gritty to punky texture where grading from claystone; slightly to noncalcareous; occasional mica and mafics; trace interlayered with shale; weak trace yellow-green sample fluorescence; very slow green-yellow cut fluorescence; very pale yellow residual cut fluorescence.

9380' SHALE - medium to dark brown; firm to hard; irregularly shaped cuttings; dominantly blocky with few tabular fragments; moderate to poor fissility; gritty to slightly arenaceous texture; dull to sparkling luster; slightly to noncalcareous; occasional mica; trace kaolinite attached; trace cuttings with slickenside appearance; trace bright white-green sample fluorescence from sandstone.

9390' MUDSTONE - medium brown; chalky; slightly firm to soft; rounded, structureless; smooth to punky texture; occasionally interlayered with shale; trace kaolinitic inclusions; slightly to noncalcareous; rare mica; no pops or odor; trace bright white-green sample fluorescence from sandstone; very slow milky yellow-green cut fluorescence; light yellow-green residual fluorescence.

9400' SAND _ clear, white, gray; fine to coarse; very angular to rounded; poor sorting; moderate to low sphericity; unconsolidated; dominantly quartz with lessor amounts of feldspar; appears immature in most places; trace free calcite and attached to shale; shale is getting more cuttings with slickensides; weak trace white-yellow sample fluorescence; very slow milky yellow cut fluorescence from trace sandstone; pale yellow residual cut fluorescence.

9410' CLAY - gray-brown; slightly thick, pasty consistency; spongy due to abundant LCM contamination; slightly sticky; moderate cohesion; good solubility; small to medium, moderately firm nodules with very poor solubility; spotty yellow-white sample fluorescence; milky yellow cut fluorescence from sandstone when crushed; light yellow residual fluorescence.

9420' MUDSTONE - brown; well indurated; smooth texture; dull luster; poor apparent porosity; occasionally slightly calcareous; slickensides; quartz; immature pops; trace very weak green-yellow cut fluorescence; very weak green-yellow residual fluorescence; pale straw visible cut.

9430' SHALE - dark brown, medium caramel brown; moderate to well indurated; crumbly to tough; blocky to tabular; earthy luster; silty lighter colored cuttings have apparent higher clay content; very slightly calcareous; occasional white calcareous veins and fracture fill; no sample fluorescence; extremely slow tinge of cut fluorescence.
